#### **D18F2x9C\_x0D0F\_E01A\_dct[0] M1 Fence Value**

Cold reset: 0000\_0000h. BIOS: [2.9.7.4.3](#). MASTER. This register is used by BIOS to temporarily store the trained fence values for the M1 memory P-state, and has no effect on the operation of the hardware. See [2.9.7.4.3](#). Note: fence2 value is recomputed by BIOS based on the fence value saved here.

| Bits  | Description                                                                                                                                                                 |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:16 | Reserved.                                                                                                                                                                   |
| 15    | Reserved. Read-write.                                                                                                                                                       |
| 14:10 | <b>TxDll: Transmit dll fence value.</b> Read-write; S3-check-exclude. BIOS saves the trained TxDll to this field until such time as it is able to write the value to NVRAM. |
| 9:5   | <b>RxDll: Receiver dll fence value.</b> Read-write; S3-check-exclude. BIOS saves the trained RxDll to this field until such time as it is able to write the value to NVRAM. |
| 4:0   | <b>TxPad: Transmit pad fence value.</b> Read-write; S3-check-exclude. BIOS saves the trained TxPad to this field until such time as it is able to write the value to NVRAM. |

## D18F2xA4 DRAM Controller Temperature Throttle

See [2.9.3 \[DCT Configuration Registers\]](#). Writes to any DCT will be broadcast to all DCTs since this logic is per DCT instance. Reads will return DCT0 result.

See [2.9.12 \[DRAM On DIMM Thermal Management and Power Capping\]](#). Independent channel throttling may still be observed by having separate EVENT\_L values.

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |      |             |       |                                |       |                          |       |                          |       |                          |       |                          |       |                          |       |                          |       |                          |       |                          |       |                          |       |                          |       |                          |       |                          |       |          |       |                                                   |       |          |

| 23:20 | <p><b>BwCapCmdThrottleMode: bandwidth capping command throttle mode.</b> Read-write. Reset: 0. Specifies the command throttle mode when BwCapEn=1. The DCT throttles commands over a rolling window of 100 clock cycles, maintaining the average throttling as specified by this field. <a href="#">MSRC001_0079</a>[BwCapCmdThrottleMode] is an alias of <a href="#">D18F2xA4</a>[BwCapCmdThrottleMode].</p> <table> <tr> <th>Bits</th><th>Description</th></tr> <tr> <td>0000b</td><td>Command throttling is disabled</td></tr> <tr> <td>0001b</td><td>Throttle commands by 30%</td></tr> <tr> <td>0010b</td><td>Throttle commands by 40%</td></tr> <tr> <td>0011b</td><td>Throttle commands by 50%</td></tr> <tr> <td>0100b</td><td>Throttle commands by 55%</td></tr> <tr> <td>0101b</td><td>Throttle commands by 60%</td></tr> <tr> <td>0110b</td><td>Throttle commands by 65%</td></tr> <tr> <td>0111b</td><td>Throttle commands by 70%</td></tr> <tr> <td>1000b</td><td>Throttle commands by 75%</td></tr> <tr> <td>1001b</td><td>Throttle commands by 80%</td></tr> <tr> <td>1010b</td><td>Throttle commands by 85%</td></tr> <tr> <td>1011b</td><td>Throttle commands by 90%</td></tr> <tr> <td>1100b</td><td>Throttle commands by 95%</td></tr> <tr> <td>1101b</td><td>Reserved</td></tr> <tr> <td>1110b</td><td>Throttle commands as specified by CmdThrottleMode</td></tr> <tr> <td>1111b</td><td>Reserved</td></tr> </table> <p>Throttling should not be enabled until after DRAM initialization (<a href="#">D18F2x110</a>[DramEnable]=1) and training (see <a href="#">2.9.7.9 [DRAM Training]</a>) are complete. | 3     | <b>MemClrInit: memory clear initialization.</b> IF ( <a href="#">D18F2x118[LockDramCfg]</a> & ~ <a href="#">D18F3x12C[OverrideLockDramCfg]</a> ) THEN Read-only. ELSE Read-write. ENDIF. 1=The node writes 0's to all locations of system memory attached to the node and sets the MemCleared bit. The status of the memory clear operation can be determined by reading the MemClrBusy and MemCleared bits. This command is ignored if MemClrBusy=1 when the command is received. DramEnable must be set before setting MemClrInit. The memory prefetcher must be disabled by setting <a href="#">D18F2x11C[PrefIoDis]</a> and <a href="#">D18F2x11C[PrefCpuDis]</a> before memory clear initialization and then can be re-enabled when MemCleared=1. Memory hole remapping must be disabled before setting MemClrInit. See <a href="#">D18F1x2[1,0][8,0][LgcyMmioHoleEn]</a> . Software may then reenale memory hole remapping when the memory clear is complete. |

### D18F2x118 Memory Controller Configuration Low

Fields in this register (bits[17:0]) indicate priority of request types. Variable priority requests enter the memory controller as medium priority and are promoted to high priority if they have not been serviced in the time specified by MctVarPriCntLmt. This feature may be useful for isochronous IO traffic. If isochronous traffic is specified to be high priority, it may have an adverse effect on the bandwidth and performance of the devices associated with the other types of traffic. However, if isochronous traffic is specified as medium priority, the processor may not meet the isochronous bandwidth and latency requirements. The variable priority allows the memory controller to optimize DRAM transactions until isochronous traffic reaches a time threshold and must be serviced more quickly.

### D18F2x11C Memory Controller Configuration High

The two main functions of this register are to control write bursting and memory prefetching.

**Write bursting.** DctWrLimit and MctWrLimit specify how writes may be burst from the MCT into the DCT to improve DRAM efficiency. When the number of writes in the MCT reaches the value specified in MctWrLimit, then they are all burst to the DCTs at once. Prior to reaching the watermark, a limited number of writes can be passed to the DCTs (specified by DctWrLimit), tagged as low priority, for the DCTs to complete when otherwise idle. Rules regarding write bursting:

- Write bursting mode only applies to low-priority writes. Medium and high priority writes are not withheld from the DCTs for write bursting.
- If write bursting is enabled, writes stay in the MCQ until the threshold specified by MctWrLimit is reached.
- Once the threshold is reached, all writes in MCQ are converted to medium priority.
- Any write in MCQ that matches the address of a subsequent access is promoted to either medium priority or the priority of the subsequent access, whichever is higher.
- DctWrLimit only applies to low-priority writes.

**Memory prefetching.** The MCT prefetcher detects stride patterns in the stream of requests and then, for predictable stride patterns, generates prefetch requests. A stride pattern is a pattern of requests through system memory that are the same number of cachelines apart. The prefetcher supports strides of -4 to +4 cachelines, which can include alternating patterns (e.g. +1, +2, +1, +2), and can prefetch 1, 2, 3, 4, or 5 cachelines ahead, depending on the confidence. In addition, a fixed stride mode (non-alternating) may be used for IO requests which often have fixed stride patterns. This mode bypasses the stride predictor such that CPU-access stride predictions are not adversely affected by IO streams.

The MCT tracks several stride patterns simultaneously. The prefetch table size is 32. Each of these has a confidence level associated with it that varies as follows:

- Each time a request is received that matches the stride pattern, the confidence level increases by one.
- Each time a request is received within +/- 4 cachelines of the last requested cacheline in the pattern that does not match the pattern, then the confidence level decreases by one.
- When the confidence level reaches the saturation point specified by PrefConfSat, then it no-longer increments.

Each request that is not within +/- 4 cachelines of the last requested cacheline line of all the stride patterns tracked initiates a new stride pattern by displacing one of the existing least-recently-used stride patterns.

The memory prefetcher uses an adaptive prefetch scheme to adjust the prefetch distance based upon the buffer space available for prefetch request data. The adaptive scheme counts the total number of prefetch requests and the number of prefetch requests that cannot return data because of buffer availability. After every 16 prefetch requests, the prefetcher uses the following rules to adjust the prefetch distance:

- If the ratio of prefetch requests that cannot return data to total prefetch requests is greater than or equal to [D18F2x1B0](#)[AdapPrefMissRatio] then the prefetch distance is reduced by [D18F2x1B0](#)[AdapPrefNega-

tiveStep].

- If the ratio of prefetch requests that cannot return data to total prefetch requests is less than **D18F2x1B0**[AdapPrefMissRatio] then the prefetch distance is increased by **D18F2x1B0**[AdapPrefPositiveStep].
- If the adjusted prefetch distance is greater than the prefetch distance defined for the current confidence level, the prefetch distance for the current confidence level is used.

The adaptive prefetch scheme supports fractional prefetch distances by alternating between two whole number prefetch distances. For example a prefetch distance of 1.25 causes a prefetch distance sequence of: 1, 1, 1, 2, 1, 1, 1, 2.

| Bits      | Description                                                                                                                                                                                                                                                                                                                                                                                                                |      |             |      |    |           |                 |      |    |     |          |

| 31        | <b>MctScrubEn: MCT scrub enable.</b> Read-write. Reset: 0. 1=Enables periodic flushing of prefetches and writes based on the DRAM scrub rate. This is used to ensure that prefetch and write data aging is not so long that soft errors accumulate and become uncorrectable. When enabled, each DRAM scrub event causes a single prefetch to be de-allocated (the oldest one) and all queued writes to be flushed to DRAM. |      |             |      |    |           |                 |      |    |     |          |
| 30        | <b>FlushWr: flush writes command.</b> Read; write-1-only; cleared-by-hardware. Reset: 0. Setting this bit causes write bursting to be canceled and all outstanding writes to be flushed to DRAM. This bit is cleared when all writes are flushed to DRAM.                                                                                                                                                                  |      |             |      |    |           |                 |      |    |     |          |
| 29        | <b>FlushWrOnStpGnt: flush writes on stop-grant.</b> Read-write. Reset: 0. BIOS: <b>~D18F2x1B4</b> [FlushWrOnS3StpGnt]. 1=Causes write bursting to be canceled and all outstanding writes to be flushed to DRAM when in the stop-grant state.                                                                                                                                                                               |      |             |      |    |           |                 |      |    |     |          |

### D18F2x1B0 Extended Memory Controller Configuration Low

The main function of this register is to control the memory prefetcher. See [D18F2x11C \[Memory Controller Configuration High\]](#) about the adaptive prefetch scheme.

**Table 164: BIOS Recommendations** for D18F2x1B[4:0]

Specifies the minimum time from a refresh command to the next valid command, except NOP or DES. The recommended programming of this register varies based on DRAM density and speed.<br><table> <tr> <th>Bits</th><th>Description</th></tr> <tr> <td>000b</td><td>Reserved</td></tr> <tr> <td>001b</td><td>90 ns (all speeds, 512 Mbit)</td></tr> <tr> <td>010b</td><td>110 ns (all speeds, 1 Gbit)</td></tr> <tr> <td>011b</td><td>160 ns (all speeds, 2 Gbit)</td></tr> <tr> <td>100b</td><td>300 ns (all speeds, 4 Gbit)</td></tr> <tr> <td>101b</td><td>350 ns (all speeds, 8 Gbit)</td></tr> <tr> <td>111b-110b</td><td>Reserved</td></tr> </table> | Bits | Description | 000b | Reserved | 001b | 90 ns (all speeds, 512 Mbit) | 010b | 110 ns (all speeds, 1 Gbit) | 011b | 160 ns (all speeds, 2 Gbit) | 100b | 300 ns (all speeds, 4 Gbit) | 101b | 350 ns (all speeds, 8 Gbit) | 111b-110b | Reserved |

| 3:0         | <b>RdPtrInit: read pointer initial value.</b> Read-write. IF ( <a href="#">BootFromDRAM</a> ) THEN Cold reset: 4h. ELSE Reset: 6h. ENDIF. BIOS: <a href="#">Table 167</a> . There is a synchronization FIFO between the NB clock domain and memory clock domain. Each increment of this field positions the read pointer one half clock cycle closer to the write pointer thereby reducing the latency through the FIFO. BIOS must program this field for the current or target NB P-state prior to a frequency change or NB P-state change. |      |             |             |          |       |            |       |            |       |             |       |             |       |             |             |             |      |          |

| 29:24       | <p><b>AggrPDDelay: aggressive power down delay.</b> Read-Write. BIOS: 20h. Specifies a hysteresis count from the last DRAM activity for the DCT to close pages prior to precharge power down. The counter does not start until the DCQ, RDQ, and WDQ are empty. The counter runs orthogonal to the page policy specified by <a href="#">D18F2x90_dct[0][DynPageCloseEn]</a>. Reserved if <a href="#">D18F2xA8_dct[0][AggrPDEn]</a>==0. See <a href="#">PchgPDEnDelay</a> and <a href="#">D18F2x94_dct[0][PowerDownEn]</a>.</p> <table> <tr> <th><u>Bits</u></th><th><u>Description</u></th></tr> <tr> <td>00h</td><td>64 clocks</td></tr> <tr> <td>01h</td><td>1 clock</td></tr> <tr> <td>3Eh-02h</td><td>&lt;AggrPDDelay&gt; clocks</td></tr> <tr> <td>3Fh</td><td>63 clocks</td></tr> </table>                                                                                                                                                                                                                                                          | <u>Bits</u> | <u>Description</u> | 00h     | 64 clocks | 01h     | 1 clock         | 3Eh-02h | <AggrPDDelay> clocks   | 3Fh | 63 clocks |

| 24:0         | <p><b>ErrCnt: error count.</b> Read; set-by-hardware; write-1-to-clear. Specifies a saturating counter indicating the number of DQ bit errors detected. Counts a maximum of 1 error per bit-lane per each bit-time. Status is accumulated until cleared by <a href="#">D18F2x250_dct[0][ResetAllErr]</a>. Errors can be masked on per-bit basis by programming <a href="#">D18F2x274_dct[0]</a>, <a href="#">D18F2x278_dct[0]</a>, and <a href="#">D18F2x27C_dct[0]</a>. IF <a href="#">D18F2x250_dct[0][LoopbackBistEn]</a> = 1, Mx_RESET_L can be used as an external trigger when an error event occurs. In this mode, a pulse at least 1 MEMCLK wide is asserted on the Mx_RESET_L pin when an error is counted. If <a href="#">D18F2x250_dct[0][StopOnErr]</a>=1, Mxx_RESET_L will be asserted until cleared by <a href="#">D18F2x250_dct[0][ResetAllErr]</a>. In this mode, if any LFSR seed is detected as all 0's then hardware writes all 1's to this field.</p> <table> <tr> <th>Bits</th><th>Description</th></tr> <tr> <td>0h</td><td>0 errors</td></tr> <tr> <td>1FF_FFFDh-1h</td><td>&lt;ErrCnt&gt; errors</td></tr> <tr> <td>1FF_FFFEh</td><td>1FF_FFFEh errors</td></tr> <tr> <td>1FF_FFFFh</td><td>1FF_FFFFh or more errors, or any LFSR seed is zero when in loopback mode</td></tr> </table> | Bits | Description | 0h      | 0 errors         | 1FF_FFFDh-1h | <ErrCnt> errors | 1FF_FFFEh | 1FF_FFFEh errors | 1FF_FFFFh | 1FF_FFFFh or more errors, or any LFSR seed is zero when in loopback mode |

| 18:0     | <p><b>DataPrbsSeed: data PRBS seed.</b> Read-write; S3-check-exclude. IF (<a href="#">BootFromDRAM</a>) THEN Cold reset: 7FFFFh. ELSE Reset: 7FFFFh. ENDIF. Specifies the seed value used for creating pseudo random traffic on the data bus. This register must be written with a non-zero seed value. PRBS23 is based on a 23 bit LFSR with polynomial <math>G(x) = x^{23} + x^{18} + 1</math>. The LFSR for each byte lane is seeded as follows: {DataPrbsSeed, 4-bit byte lane index}. PRBS bits [7:0] map to byte lane bits [7:0]. Recommended BIOS values for DRAM training:</p> <table> <tr> <th>CmdCount</th><th>DataPrbsSeed</th></tr> <tr> <td>32</td><td>62221h</td></tr> <tr> <td>64</td><td>66665h</td></tr> <tr> <td>128</td><td>26666h</td></tr> <tr> <td>256</td><td>44443h</td></tr> </table> | CmdCount | DataPrbsSeed | 32 | 62221h | 64 | 66665h | 128 | 26666h | 256 | 44443h |

| 0    | <b>EffArbDis: Efficient arbitration disable.</b> Read-write. IF ( <a href="#">BootFromDRAM</a> ) THEN Cold reset: 0. ELSE Reset: 0. ENDIF. BIOS: 0. 0=The DCT optimizes the arbitration phases to improve performance (in addition to EarlyArbEn=1, this applies to non-page-hit DRAM commands) under certain traffic conditions whenever the NCLK to MEMCLK ratio is less than 2:1. The DCT arbitrates normally with other ratios. 1=The DCT arbitrates normally, requiring 3 NCLKs, at all NCLK:MEMCLK ratios. If the NCLK to MEMCLK ratio is less than 2:1, the DCT issues non-PH commands at most every other MEMCLK cycle. |

IF ([BootFromDRAM](#)) THEN Cold reset: 0000\_0404h. ELSE Reset: 0000\_0000h. ENDIF. See 2.9.3 [DCT Configuration Registers].

The GMC to DCT interface (GARLIC) controls how DRAM bus resources are allocated and arbitrated between the MCT and the GMC. A token is the unit of available resource and is equivalent to a DCQ entry. A minimum count ensures a number of available DCQ entries. A token limit for MCT or GMC ensures resources are not all allocated to the GMC, or MCT respectively. Limits are configured bimodal: for normal GMC traffic and for when urgent (nominally display refresh) GMC traffic is occurring.

| 26    | <b>NbArrayParEn: northbridge array parity error reporting enable.</b> 1=Enables reporting of parity errors in the NB arrays.                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 25    | <b>UsPwDatErrEn: upstream data error enable.</b> Read-write. 1=Enables MCA reporting of upstream posted writes in which the EP bit is set as indicated by the ONION error bits.                                                                                                                                                                                                                                                                                                                                                                                           |
| 24:18 | Unused. Read-write.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 17    | <b>CpPktDatEn: completion packet error reporting enable.</b> Read-write. 1=Enables MCA reporting of completion packets with the EP bit set. Any response packet with data errors detected by ONION will generate this error.                                                                                                                                                                                                                                                                                                                                              |
| 16    | <b>NbIntProtEn: northbridge internal bus (ONION) protocol error reporting enable.</b> Read-write. 1=Enables MCA reporting of protocol errors detected on the northbridge internal bus (ONION). When possible, this enable should be cleared before initiating a warm reset to avoid logging spurious errors due to RESET_L signal skew.                                                                                                                                                                                                                                   |
| 15:13 | Unused. Read-write.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 12    | <b>WDTRptEn: watchdog timer error reporting enable.</b> 1=Enables MCA reporting of watchdog timer errors. The watchdog timer checks for NB system accesses for which a response is expected but no response is received. See <a href="#">D18F3x44 [MCA NB Configuration]</a> for information regarding configuration of the watchdog timer duration. This bit does not affect operation of the watchdog timer in terms of its ability to complete an access that would otherwise cause a system hang. This bit only affects whether such errors are reported through MCA. |
| 11    | <b>AtomicRMWEn: atomic read-modify-write error reporting enable.</b> 1=Enables MCA reporting of atomic read-modify-write (RMW) commands received from an IO link. Atomic RMW commands are not supported. An atomic RMW command results in a link error response being generated back to the requesting IO device. The generation of the link error response is not affected by this bit.                                                                                                                                                                                  |
| 10    | Unused. Read-write.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 9     | <b>TgtAbortEn: target abort error reporting enable.</b> 1=Enables MCA reporting of target aborts to a link. The NB returns an error response back to the requestor with any associated data all 1s independent of the state of this bit.                                                                                                                                                                                                                                                                                                                                  |
| 8     | <b>MstrAbortEn: master abort error reporting enable.</b> 1=Enables MCA reporting of master aborts to a link. The NB returns an error response back to the requestor with any associated data all 1s independent of the state of this bit.                                                                                                                                                                                                                                                                                                                                 |

| 4:2 | Unused. Read-write.                                                                                                                                                                                                                                                                                       |
| 1   | <b>UECCEn: uncorrectable ECC error reporting enable.</b> 1=Enables MCA reporting of DDR3 DRAM uncorrectable ECC errors which are detected in the NB. In some cases data may be forwarded to the core prior to checking ECC in which case the check takes place in one of the other error reporting banks. |
| 0   | <b>CECCEn: correctable ECC error reporting enable.</b> 1=Enables MCA reporting of DDR3 DRAM correctable ECC errors which are detected in the NB.                                                                                                                                                          |

### D18F3x44 MCA NB Configuration

See [D18F3x180 \[Extended NB MCA Configuration\]](#). It is expected that all fields of this register are programmed to the same value in all nodes, except for the fields used for link error injection: GenLinkSel, GenSubLinkSel, GenCrcErrByte1, GenCrcErrByte0.

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

BIOS: 1.<br>1=Enable sync flood of all links with sync packets on detection of an uncorrectable DRAM ECC error.                                                                                                                                                                                                                                                                  |
| 1 | <b>CpuRdDatErrEn: CPU read data error log enable.</b> Read-write. Reset: 0. 1=Enables reporting of read data errors (master aborts and target aborts) for data destined for the CPU on this node. This bit should be clear if read data error logging is enabled for the remaining error reporting blocks in the CPU. Logging the same error in more than one block may cause a single error event to be treated as a multiple error event and cause the CPU to enter shutdown. |

**D18F3x58 Scrub Rate Control**

This register specifies the ECC sequential scrubbing rate for lines of memory and cache. See 2.8.3 [Memory Scrubbers]. Scrub rates are a platform consideration. See 2.14.1.8 [Scrub Rate Considerations].

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |         |             |      |             |     |                              |     |         |     |                    |     |         |     |                    |     |         |     |                     |     |          |     |                     |     |          |     |        |     |       |     |         |     |       |     |         |         |          |     |         |     |       |     |         |  |  |     |         |  |  |     |         |  |  |     |         |  |  |     |          |  |  |     |          |  |  |     |          |  |  |

|       | 1. This setting is not supported (and is not verified) except as a DRAM scrub rate when no other memory accesses are being performed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |         |             |      |             |     |                              |     |         |     |                    |     |         |     |                    |     |         |     |                     |     |          |     |                     |     |          |     |        |     |       |     |         |     |       |     |         |         |          |     |         |     |       |     |         |  |  |     |         |  |  |     |         |  |  |     |         |  |  |     |          |  |  |     |          |  |  |     |          |  |  |

**D18F3x5C DRAM Scrub Address Low**

In addition to sequential DRAM scrubbing, the DRAM scrubber has a redirect mode for scrubbing DRAM locations accessed during normal operation. This is enabled by setting [D18F3x5C](#)[ScrubReDirEn]. When a DRAM read is generated by any agent other than the DRAM scrubber, correctable ECC errors are corrected as the data is passed to the requestor, but the data in DRAM is not corrected if redirect scrubbing mode is disabled. In scrubber redirect mode, correctable errors detected during normal DRAM read accesses redirect the scrubber to the location of the error. After the scrubber corrects the location in DRAM, it resumes scrubbing from where it left off. DRAM scrub address registers are not modified by the redirect scrubbing

mode. Sequential scrubbing and scrubber redirection can be enabled independently or together. ECC errors detected by the scrubber are logged in the MCA registers (See [D18F3x40 \[MCA NB Control\]](#)).

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:6 | <b>ScrubAddr[31:6]: DRAM scrubber address bits[31:6].</b> Read-write; updated-by-hardware. ScrubAddr[47:6] = { <a href="#">D18F3x60[ScrubAddr[47:32]]</a> , ScrubAddr[31:6]}. Reset: 0. ScrubAddr points to a DRAM cacheline in physical address space. BIOS should initialize the scrubber address register to the base address of the node specified by <a href="#">D18F1x[17C:140,7C:40] [DRAM Base/Limit]</a> prior to enabling sequential scrubbing through <a href="#">D18F3x58[DrumScrub]</a> . When sequential scrubbing is enabled: it starts at the address that the scrubber address registers are initialized to; it increments through address space and updates the scrubber address registers as it does so; when the scrubber reaches the DRAM limit address specified by <a href="#">D18F1x[17C:140,7C:40]</a> , it wraps around to the base address. Reads of the scrubber address registers provide the next cacheline to be scrubbed.     |
| 5:1  | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 0    | <b>ScrubReDirEn: DRAM scrubber redirect enable.</b> Read-write. Reset: 0. BIOS: See <a href="#">Table 47 [DCT Training Specific Register Values]</a> . If a correctable error is discovered from a non-scrubber DRAM read, then the data is corrected before it is returned to the requestor; however, the DRAM location may be left in a corrupted state (until the next time the scrubber address counts up to that location, if sequential scrubbing is enabled through <a href="#">D18F3x58[DrumScrub]</a> ). 1=Enables the scrubber to immediately scrub any address in which a correctable error is discovered. This bit and sequential scrubbing can be enabled independently or together; if both are enabled, the scrubber jumps from the scrubber address to where the correctable error was discovered, scrubs that location, and then jumps back to where it left off; the scrubber address register is not affected during scrubber redirection. |

### D18F3x60 DRAM Scrub Address High

### D18F3x64 Hardware Thermal Control (HTC)

See [2.10.3.1 \[PROCHOT\\_L and Hardware Thermal Control \(HTC\)\]](#). If Fuse[HtcMsrLock]=1, then HtcPstateLimit, HtcHystLmt, HtcTmpLmt, HtcClkInact, HtcClkAct, HtcPstateSel, and HtcEn fields are reserved. [MSRC001\\_003E](#) is an alias of [D18F3x64](#). If [D18F3xE8\[HtcCapable\]](#)=0 then this register is reserved.

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

### D18F3x6C Data Buffer Count

Out of cold reset, the processor allocates a minimal number of buffers that is smaller than the default values in the register. BIOS must use [D18F0x6C\[RlsLnkFullTokCntImm\]](#) or [D18F0x6C\[RlsLnkFullTokCntOnRst\]](#) for the values in the register to take effect. This is necessary even if the values are unchanged from the default values.

- To ensure deadlock free operation the following minimum buffer allocations are required:
  - Rule: [D18F3x6C\[UpRspDBC\]](#)  $\geq 1$ .
  - Rule: [D18F3x6C\[DnReqDBC\]](#)  $\geq 1$ .
  - Rule: [D18F3x6C\[UpReqDBC\]](#)  $\geq 1$ .
  - Rule: [D18F3x6C\[DnRspDBC\]](#)  $\geq 1$ .
- If [D18F0x\[E4,C4,A4,84\]\[IsocEn\]](#)=1: [IsocRspDBC](#)  $\geq 1$ .
- The total number of data buffers allocated in this register and [D18F3x7C](#) must satisfy the following equation:
  - Rule: [D18F3x6C\[UpReqDBC\]](#) + [D18F3x6C\[UpRspDBC\]](#) + [D18F3x6C\[DnReqDBC\]](#) + [D18F3x6C\[DnRspDBC\]](#) + [D18F3x6C\[IsocRspDBC\]](#) + (IF ([D18F3x7C\[Sri2XbarFreeRspDBC\]](#)==0) THEN ([D18F3x7C\[Sri2XbarFreeXreqDBC\]](#)\*2) ELSE [D18F3x7C\[Sri2XbarFreeXreqDBC\]](#) ENDIF) + [D18F3x7C\[Sri2XbarFreeRspDBC\]](#)  $\leq 16$ .

| Bits  | Description                                                                               |

### D18F3x74 XBAR to SRI Command Buffer Count

Reset: 0007\_1111h. Out of cold reset, the processor allocates a minimal number of buffers that is smaller than the default values in the register. BIOS must use  $D18F0x6C[RlsLnkFullTokCntImm]$  or  $D18F0x6C[RlsLnkFullTokCntOnRst]$  for the values in the register to take effect. This is necessary even if the values are unchanged from the default values.

**Table 172: Buffer Definitions**

| Term            | Definition                                                                |
|-----------------|---------------------------------------------------------------------------|
| <b>SpqSize</b>  | Probe command queue size.<br>SpqSize = 20.                                |
| <b>SrqSize</b>  | SRQ (XBAR command and probe response to SRI) queue size.<br>SrqSize = 36. |
| <b>PrbRsp</b>   | SRQ entries hard allocated to probe responses. PrbRsp = 4.                |
| <b>MpbcSize</b> | MPB command buffer size.<br>MpbcSize = 24.                                |
| <b>McqSize</b>  | MCT command queue size.<br>McqSize = 36.                                  |

- To ensure deadlock free operation the following minimum buffer allocations are required:
  - Rule:  $D18F3x74[ProbeCBC] \geq 2$ .
  - Rule:  $D18F3x74[UpReqCBC] \geq 1$ .
  - Rule:  $D18F3x74[UpPreqCBC] \geq 1$ .
  - $(IsocReqCBC + IsocPreqCBC + DRReqCBC) \leq 31$ .
  - $(IsocReqCBC + IsocPreqCBC + DRReqCBC) \leq (McqSize - 16)$ .
- If any of  $D18F0x[E4,C4,A4,84][IsocEn]$  bits are set, then  $IsocReqCBC \geq 1$ .
- If any of the  $D18F0x[E4,C4,A4,84][IsocEn]$  bits are set and isochronous posted requests may be generated by the system:  
 $IsocPreqCBC \geq 1$
- The total number of XBAR to SRI command buffers allocated in this register and  $D18F3x7C$  must satisfy the following equation:
  - Rule:  $D18F3x74[UpReqCBC] + D18F3x74[UpPreqCBC] + D18F3x74[DnReqCBC] + D18F3x74[DnPreqCBC] + D18F3x74[IsocReqCBC] + D18F3x74[IsocPreqCBC] + D18F3x74[DRReqCBC] + D18F3x7C[Xbar2SriFreeListCBC] + (D18F3x1A0[CpuCmdBufCnt] * NumOfCompUnitsOnNode) + D18F3x1A0[CpuToNbFreeBufCnt] + PrbRsp \leq SrqSize$
- The total number of SPQ (probe command) buffers allocated must satisfy the following equation:
  - Rule:  $(D18F3x17C[SPQPrbFreeCBC] + D18F3x74[ProbeCBC]) \leq SpqSize$ .

| Bits  | Description                                                                               |

### D18F3x78 MCT to XBAR Buffer Count

Reset: 0024\_0519h. Out of cold reset, the processor allocates a minimal number of buffers that is smaller than the default values in the register. BIOS must use [D18F0x6C\[RlsLnkFullTokCntImm\]](#) or [D18F0x6C\[RlsLnkFullTokCntOnRst\]](#) for the values in the register to take effect. This is necessary even if the values are unchanged from the default values.

- To ensure deadlock free operation the following minimum buffer allocations are required:  
 $\text{ProbeCBC} \geq 1$                        $\text{RspCBC} \geq 1$                        $\text{RspDBC} \geq 2$   
 $\text{RspDBC} \geq \text{D18F2x11C}[\text{MctPrefReqLimit}] + 2$
- The total number of command buffers allocated in this register must satisfy the following equation:  
Rule:  $(\text{D18F3x78}[\text{ProbeCBC}] + \text{D18F3x78}[\text{RspCBC}]) \leq \text{MpbcsSize}$ .

### D18F3x7C Free List Buffer Count

Reset: 0003\_660Ch. Out of cold reset, the processor allocates a minimal number of buffers that is smaller than the default values in the register. BIOS must use [D18F0x6C\[RlsLnkFullTokCntImm\]](#) or [D18F0x6C\[RlsLnkFullTokCntOnRst\]](#) for the values in the register to take effect. This is necessary even if the values are unchanged from the default values. See [D18F3x6C](#) and [D18F3x70](#).

- To ensure deadlock free operation the following minimum buffer allocations are required:
  - Rule: IF ([D18F3x7C\[Sri2XbarFreeRspCBC\]](#)==0) THEN ([D18F3x7C\[Sri2XbarFreeXreqCBC\]](#)>2).
  - Rule: IF ([D18F3x7C\[Sri2XbarFreeRspCBC\]](#)!=0) THEN ([D18F3x7C\[Sri2XbarFreeRspCBC\]](#)>2).
  - Rule: IF ([D18F3x7C\[Sri2XbarFreeRspDBC\]](#)==0) THEN ([D18F3x7C\[Sri2XbarFreeXreqDBC\]](#)>2).
  - Rule: IF ([D18F3x7C\[Sri2XbarFreeRspDBC\]](#)!=0) THEN ([D18F3x7C\[Sri2XbarFreeRspDBC\]](#)>2).
  - Rule: [D18F3x7C\[Xbar2SriFreeListCBC\]](#) >= ([D18F3x1A0\[CpuToNbFreeBufCnt\]](#) \* [NumOfCompUnitsOnNode](#)) + 2.

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                                         |

### D18F3x[84:80] ACPI Power State Control

This block consists of eight identical 8-bit registers, one for each System Management Action Field (SMAF) code associated with STPCLK assertion commands from the link. Refer to the descriptions below for the associated ACPI state and system management actions for each of the 8 SMAF codes. The SmafAct fields specify the system management actions taken when the corresponding SMAF code is received. For instance, a SMAF code of 5 results in the power management actions specified by SmafAct5. Some ACPI states and associated SMAF codes may not be supported in certain conditions. See [2.5 \[Power Management\]](#) for which states are supported.

When a link STPCLK assertion command is received by the processor, the power management commands specified by the register with the corresponding SMAF code are invoked. When the STPCLK deassertion command is received by the processor, the processor returns into the operational state. However, had the NB COF-change command been issued (NbCofChg), the NB returns in the new NB P-state.

In multi-node systems, these registers should be programmed identically in all nodes.

**Table 173: SMAF Action Definition**

| Register                         | SmafAct  | ACPI state             | Description                                                                                                                                                                                                                                                      |
|----------------------------------|----------|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">D18F3x84</a> [31:24] | SmafAct7 | C1                     | Initiated when a Halt instruction is executed by processor. This does not involve the interaction with the SMC, therefore the SMC is required to never send STPCLK assertion commands with SMAF=7h.                                                              |
| <a href="#">D18F3x84</a> [23:16] | SmafAct6 | S4/S5                  | Initiated by a processor access to the ACPI-defined PM1_CNTa register.                                                                                                                                                                                           |
| <a href="#">D18F3x84</a> [15:8]  | SmafAct5 | Throttling             | Occurs based upon SMC hardware-initiated throttling. Refer to section <a href="#">1.5.4 [Supported Feature Variations]</a> for package-specific support. AMD recommends using PROCHOT_L for thermal throttling and not implementing stop clock based throttling. |
| <a href="#">D18F3x84</a> [7:0]   | SmafAct4 | S3                     | Initiated by a processor access to the ACPI-defined PM1_CNTa register.                                                                                                                                                                                           |
| <a href="#">D18F3x80</a> [31:24] | SmafAct3 | S1                     | Initiated by a processor access to the ACPI-defined PM1_CNTa register.                                                                                                                                                                                           |
| <a href="#">D18F3x80</a> [23:16] | SmafAct2 | -                      |                                                                                                                                                                                                                                                                  |
| <a href="#">D18F3x80</a> [15:8]  | SmafAct1 | C3, C1E, or Link init. | Initiated by an access to the ACPI-defined P_LVL3 register.                                                                                                                                                                                                      |
| <a href="#">D18F3x80</a> [7:0]   | SmafAct0 | C2                     | Initiated by a processor access to the ACPI-defined P_LVL2 register.                                                                                                                                                                                             |

### D18F3x80 ACPI Power State Control Low

Reset: 0000\_0000h. Read-write.

| 7     | <b>PsiVidEn: PSI_L VID enable.</b> Read-write. Reset: 0. BIOS: <a href="#">2.5.1.3.1.1</a> . This bit specifies how PSI_L is controlled. This signal may be used by the voltage regulator to improve efficiency while in reduced power states. 1=Control over the PSI_L signal is as specified by the PsiVid field of this register. 0=PSI_L is always high. See <a href="#">2.5.1.3.1 [PSIx_L Bit]</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |      |             |      |             |      |      |      |      |      |      |      |       |      |      |      |          |      |      |      |          |
| 6:0   | <b>PsiVid[6:0]: PSI_L VID threshold.</b> Read-write. Reset: 0. BIOS: <a href="#">2.5.1.3.1.1</a> . PsiVid[7:0] = {PsiVid[7], PsiVid[6:0]}. When enabled by PsiVidEn, PsiVid[7:0] specifies the threshold value of the VID code generated by the processor, which in turn determines the state of PSI0_L. When the VID code generated by the processor is less than PsiVid[7:0] (i.e., the VID code is specifying a higher voltage level than the PsiVid-specified voltage level), then PSI0_L is high; when the VID code is greater than or equal to PsiVid[7:0], PSI0_L is driven low. See <a href="#">2.5.1.3.1 [PSIx_L Bit]</a> .                                                                                                                                                                                                                                                                                                                                          |      |             |      |             |      |      |      |      |      |      |      |       |      |      |      |          |      |      |      |          |

### D18F3xA4 Reported Temperature Control

The slew rate controls in this register are used to filter processor temperature measurements. Separate controls are provided for a measured temperature, Tctlm, that is higher or lower than Tctl. The per-step timer counts as long as the measured temperature stays either above or below Tctl. Each time the measured temperature changes to the other side of Tctl, the step timer resets, and Tctl is not changed. If, for example, step times are enabled in both directions, Tctl=62.625, and the measured temperature keeps jumping quickly between 62.5 and 63.0, then (assuming the step times are long enough) Tctl would not change. However, once the measured temperature settles on one side of Tctl, Tctl can step toward the measured temperature. If the difference of measured temperature minus Tctl is greater than the value set by MaxTmpDiffUp, then Tctl is set equal to the measured temperature. See [2.10 \[Thermal Functions\]](#).

| Bits      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                     |                 |             |                                           |     |           |      |           |         |                                                                                                                                                                                                                                                                                                                                                                     |   |                     |      |   |         |      |   |   |      |   |       |           |   |                |      |   |         |

| 11b       | CurTmp is a read-write register that specifies a value used to create Tctl. The two LSB's are read-only zero (provides 0.5 degree resolution). Value in CurTmp is passed through slew control logic. That result is used for HTC and SB-TSI. However, the value reported through CurTmp is the same as the input value and is unaffected by the slew control logic.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                     |                 |             |                                           |     |           |      |           |         |                                                                                                                                                                                                                                                                                                                                                                     |   |                     |      |   |         |      |   |   |      |   |       |           |   |                |      |   |         |

### D18F3xA8 Pop Up and Down P-states

| Bits  | Description                                                                                                                                                                                                                                                                     |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:29 | <b>PopDownPstate.</b> Read-write. Reset: D18F3xDC[HwPstateMaxVal]. BIOS: D18F3xDC[HwPstateMaxVal]. Specifies the pop-down P-state number. This field uses hardware P-state numbering. See 2.5.3.2.3.3 [Core C6 (CC6) State]. This field must be set to D18F3xDC[HwPstateMaxVal] |

### D18F3xB8 NB Array Address

S3-check-exclude. Reset: xxxx\_xxxxh. D18F3xB8 [NB Array Address] and D18F3xBC [NB Array Data Port] provide a mechanism to inject errors into DRAM and data read from internal NB arrays.

D18F3xB8 should first be written with the target array and address within the array. Read and write accesses to D18F3xBC then access the target address within the target array.

| Bits        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |             |             |    |                                                                |    |                                                                          |    |                                                                |            |          |

**D18F3xBC\_x8 DRAM ECC**

This register controls injection of errors in writes to DRAM. See [2.14.3.1 \[DRAM Error Injection\]](#).

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |     |             |     |            |     |             |     |             |     |             |     |             |     |             |     |              |     |               |     |           |

| 18    | <b>DramErrEn.</b> Read-write. Reset: 0. 1=Errors are continually injected on DRAM writes. The error injection takes place only on DRAM write accesses and should be initiated by a non-cacheable store. Errors continue to be injected on writes until this bit is cleared to a 0 by software.                                                                                                                                                                                                                                                                                                                                                   |     |             |     |            |     |             |     |             |     |             |     |             |     |             |     |              |     |               |     |           |
| 17    | <b>EccWrReq.</b> Read; write-1-only; cleared-by-hardware. Reset: 0. 1=Error is injected on DRAM write at the bits enabled by ErrInjEn and EccVector. A single error injection takes place on the next DRAM write access and should be initiated by a non-cacheable store. This bit is cleared by hardware after the write.                                                                                                                                                                                                                                                                                                                       |     |             |     |            |     |             |     |             |     |             |     |             |     |             |     |              |     |               |     |           |
| 16    | <b>EccRdReq.</b> Read; write-1-only; cleared-by-hardware. Reset: 0. 1=Indicates a DRAM ECC read is requested. The read takes place on the next DRAM read access and should be initiated by a non-cacheable load. The ECC bits read from DRAM are stored in EccVector. This bit is cleared by hardware after the read.                                                                                                                                                                                                                                                                                                                            |     |             |     |            |     |             |     |             |     |             |     |             |     |             |     |              |     |               |     |           |
| 15:0  | <b>EccVector: error injection vector.</b> Read-write; S3-check-exclude. Reset: x. When used in conjunction with EccWrReq, each bit of EccVector enables injecting errors to the corresponding bit within each word enabled by ErrInjEn. When used in conjunction with EccRdReq, EccVector holds the contents of the DRAM ECC bits after the read.                                                                                                                                                                                                                                                                                                |     |             |     |            |     |             |     |             |     |             |     |             |     |             |     |              |     |               |     |           |

| 30:28       | <p><b>NbClkDiv: NB clock divisor.</b> Read-write. Cold reset: Fuse[NbDivAltVid]. BIOS: 001b.</p> <p>Specifies the NB CLK divisor associated with <a href="#">D18F3x80/D18F3x84</a>[NbLowPwrEn]. This divisor is applied while LDTSTOP_L is asserted if the corresponding core CLK divisor, <a href="#">D18F3x80/D18F3x84</a>[ClkDivisor], is set to “turn off clocks” or if NBClkDivApplyAll=1; otherwise, the divisor specified by <a href="#">D18F3x80/D18F3x84</a>[ClkDivisor] is applied. This divisor is relative to the current NB FID frequency, or:</p> <p>100 MHz * (4 + <a href="#">D18F5x16</a>[C:0][NbFid]).</p> <p>If <a href="#">D18F5x16</a>[C:0][NbDid] of the current NB P-state indicates a divisor that is lower than specified by this field, then no NB frequency change is made when entering the low-power state associated with this register (i.e., if this field specifies a divide-by 1 and the DID is divide-by 2, then the divisor remains 2 while in the low-power state). This field is encoded as follows:</p> <table><tr><td><u>Bits</u></td><td><u>Description</u></td><td><u>Bits</u></td><td><u>Description</u></td></tr><tr><td>000b</td><td>Divide-by 1</td><td>100b</td><td>Divide-by 16</td></tr><tr><td>001b</td><td>Divide-by 2</td><td>101b</td><td>Reserved Divide-by 128</td></tr><tr><td>010b</td><td>Divide-by 4</td><td>110b</td><td>Reserved Divide-by 512</td></tr><tr><td>011b</td><td>Divide-by 8</td><td>111b</td><td>Reserved</td></tr></table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | <u>Bits</u> | <u>Description</u>     | <u>Bits</u> | <u>Description</u> | 000b  | Divide-by 1      | 100b  | Divide-by 16 | 001b  | Divide-by 2      | 101b  | Reserved Divide-by 128 | 010b  | Divide-by 4      | 110b  | Reserved Divide-by 512 | 011b  | Divide-by 8 | 111b  | Reserved        |       |       |       |                 |       |       |       |                 |       |       |       |                 |       |       |       |                 |

| 27:24       | <p><b>PowerStepUp.</b> Read-write. Reset: 0000b. Specifies the rate at which blocks of compute unit and NB logic are gated on while the processor transitions from a quiescent state to an active state as part of a power management state transition. There are about 15 steps in this transition for each compute unit and about 5 steps for the NB for the PowerStepDown and PowerStepUp transitions. So the total transition time for a single compute unit is about 15 times the time specified by PowerStepDown and PowerStepUp and the transition time for the NB is about 5 times the time specified by PowerStepDown and PowerStepUp. Use of longer transition times may help reduce voltage transients associated with power state transitions. The bits for PowerStepUp and PowerStepDown are encoded as follows:</p> <table><tr><td><u>Bits</u></td><td><u>Description</u></td><td><u>Bits</u></td><td><u>Description</u></td></tr><tr><td>0000b</td><td>Reserved. 400 ns</td><td>1000b</td><td>50 ns</td></tr><tr><td>0001b</td><td>Reserved. 300 ns</td><td>1001b</td><td>Reserved. 45 ns</td></tr><tr><td>0010b</td><td>Reserved. 200 ns</td><td>1010b</td><td>Reserved. 40 ns</td></tr><tr><td>0011b</td><td>100 ns</td><td>1011b</td><td>Reserved. 35 ns</td></tr><tr><td>0100b</td><td>90 ns</td><td>1100b</td><td>Reserved. 30 ns</td></tr><tr><td>0101b</td><td>80 ns</td><td>1101b</td><td>Reserved. 25 ns</td></tr><tr><td>0110b</td><td>70 ns</td><td>1110b</td><td>Reserved. 20 ns</td></tr><tr><td>0111b</td><td>60 ns</td><td>1111b</td><td>Reserved. 15 ns</td></tr></table> <ul style="list-style-type: none"><li>• If PowerStepDown or PowerStepUp are programmed to greater than 50 ns, then the value applied to the NB is clipped to 50 ns. The compute unit steps are not clipped.</li><li>• PowerStepDown and PowerStepUp should always be configured to less than or equal to 50 ns in client systems. This restriction is to satisfy display refresh and isoc bandwidth requirements.</li><li>• BIOS: 1000b.</li></ul> | <u>Bits</u> | <u>Description</u>     | <u>Bits</u> | <u>Description</u> | 0000b | Reserved. 400 ns | 1000b | 50 ns        | 0001b | Reserved. 300 ns | 1001b | Reserved. 45 ns        | 0010b | Reserved. 200 ns | 1010b | Reserved. 40 ns        | 0011b | 100 ns      | 1011b | Reserved. 35 ns | 0100b | 90 ns | 1100b | Reserved. 30 ns | 0101b | 80 ns | 1101b | Reserved. 25 ns | 0110b | 70 ns | 1110b | Reserved. 20 ns | 0111b | 60 ns | 1111b | Reserved. 15 ns |

| 11:8 | <b>ClkRampHystSel: clock ramp hysteresis select.</b> Read-write. Reset: 0h. Char.BIOS: Fh. When the core(s) are in the stop-grant or halt state and a probe request is received, the core clock may need to be brought up to service the probe. <ul style="list-style-type: none"> <li>• If (<a href="#">D18F4x128[CoreCstateMode]</a> ? (<a href="#">D18F3x80/D18F3x84[CpuPrbEn]</a>==0) : (<a href="#">D18F4x118/D18F4x11C[CpuPrbEn]</a>==0)) then this field specifies how long the core clock is left up to service additional probes before being brought back down. Each time a probe request is received, the hysteresis timer is reset such that the period of time specified by this field must expire with no probe request before the core clock is brought back down. The hysteresis time is encoded as (the time base specified by <a href="#">D18F3xD4[ClkRampHystCtl]</a>) * (1 + <a href="#">ClkRampHystSel</a>).</li> <li>• If (<a href="#">D18F4x128[CoreCstateMode]</a> ? (<a href="#">D18F3x80/D18F3x84[CpuPrbEn]</a>==1) : (<a href="#">D18F4x118/D18F4x11C[CpuPrbEn]</a>==1)) then this field specifies a fixed amount of time to allow for probes to be serviced after completing the transition of each core. If, for example, two cores enter stop-grant or halt at the same time, then (1) the first core would complete the transition to the low power state, (2) probe traffic would be serviced for the time specified by this field, (3) the second core would complete the transition to the low power state, and (4) probe traffic would be serviced for the time specified by this field (and afterwards, until the next power state transition). For this purpose, values range from 0h=40 ns to Fh=640 ns, encoded as 40 ns * (1 + <a href="#">ClkRampHystSel</a>).</li> </ul> |

| 5:0  | <b>MaxSwPstateCpuCof: maximum software P-state core COF.</b> Read-only. Cold reset: <a href="#">Fuse[MaxSwPstateCof]</a> . Specifies the maximum CPU COF supported by the processor in a software P-state. The maximum frequency is 100 MHz * <a href="#">MaxSwPstateCpuCof</a> , if <a href="#">MaxSwPstateCpuCof</a> is greater than zero; if <a href="#">MaxSwPstateCpuCof</a> = 00h, then there is no frequency limit. Any attempt to change a software P-state CPU COF to a frequency greater than specified by this field is ignored. Processors that support core performance boost must fuse this field to the software P0 frequency or higher. See <a href="#">2.5.3.1.1.1 [Software P-state Numbering]</a> and <a href="#">2.5.3.1.5 [Core P-state Transition Behavior]</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## D18F3xD8 Clock Power/Timing Control 1

| 14:12 | <p><b>NbsynPtrAdj: NB/core synchronization FIFO pointer adjust.</b> Read-write. Cold reset: 000b. BIOS: 110b.</p> <p>Changes to this field take effect after any of the following events :</p> <ul style="list-style-type: none"> <li>• Warm reset.</li> <li>• At least one core on all compute units perform a P-state transition.</li> <li>• An NB P-state transition.</li> </ul> <p>There is a synchronization FIFO between the NB clock domain and core clock domains. At cold reset, the read pointer and write pointer for each of these FIFOs is positioned conservatively, such that FIFO latency may be greater than is necessary.</p> <p>NbsynPtrAdj and NbsynPtrAdjLo may be used to position the read pointer and write pointer of each FIFO closer to each other such that latency is reduced. Each increment of NbsynPtrAdj and NbsynPtrAdjLo represents one clock cycle of whichever is the slower clock (longer period) between the NB clock and the core clock. NbsynPtrAdj is used when the core P-state is less than or equal to NbsynPtrAdjPstate, otherwise NbsynPtrAdjLo is used.</p> <p>Values less than the recommended value are allowed; values greater than the recommended value are illegal.</p> <table> <tr> <th>Bits</th><th>Description</th></tr> <tr> <td>6h-0h</td><td>Position the read pointer &lt;NbsynPtrAdj, NbsynPtrAdjLo&gt; clock cycles closer to the write pointer.</td></tr> <tr> <td>7h</td><td>Position the read pointer 7 clock cycles closer to the write pointer</td></tr> </table> | Bits | Description | 6h-0h | Position the read pointer <NbsynPtrAdj, NbsynPtrAdjLo> clock cycles closer to the write pointer. | 7h   | Position the read pointer 7 clock cycles closer to the write pointer |      |             |      |             |      |              |      |                        |      |                        |      |                 |

## D18F3x140 SRI to XCS Token Count

Out of cold reset, the processor allocates a minimal number of buffers that is smaller than the default values in the register. BIOS must use [D18F0x6C\[RlsLnkFullTokCntImm\]](#) or [D18F0x6C\[RlsLnkFullTokCntOnRst\]](#) for the values in the register to take effect. This is necessary even if the values are unchanged from the default values.

[D18F3x140](#), [D18F3x144](#), and [D18F3x1\[54:48\]](#) specify the number of XCS (XBAR command scheduler) entries assigned to each virtual channel within each source port. See [2.8 \[Northbridge \(NB\)\]](#).

The default totals are:

Buffer allocation rules:

- The totals of SRI, MCT and the links must not exceed the number of XCS entries.  $XcsSize = 44$ .
  - Rule:  $SUM(D18F3x140[UpReqTok, UpPreqTok, UpRspTok, DnReqTok, DnPreqTok, DnRspTok, IsocReqTok, IsocPreqTok, IsocRspTok, FreeTok]) + SUM(D18F3x144[ProbeTok, RspTok]) + SUM(D18F3x148[ReqTok0, PReqTok0, RspTok0, ProbeTok0, \{FreeTok[3:2], FreeTok[1:0]\}, IsocReqTok0, IsocPreqTok0, IsocRspTok0, ReqTok1, PReqTok1, RspTok1, ProbeTok1, IsocReqTok1, IsocPreqTok1, IsocRspTok1]) + SUM(D18F3x14C[ReqTok0, PReqTok0, RspTok0, ProbeTok0, \{FreeTok[3:2], FreeTok[1:0]\}, IsocReqTok0, IsocPreqTok0, IsocRspTok0, ReqTok1, PReqTok1, RspTok1, ProbeTok1, IsocReqTok1, IsocPreqTok1, IsocRspTok1]) \leq XcsSize$ . See [D18F3x1\[54:48\]](#).

The defaults for [D18F3x140](#) and [D18F3x1\[54:48\]](#) do not allocate any tokens in the isochronous channel. If isochronous flow control mode (IFCM) is enabled ([D18F0x\[E4,C4,A4,84\]\[IsocEn\]](#)), then the XCS token counts must be changed.

- If IFCM is enabled, then [D18F3x140\[IsocReqTok, IsocRspTok\]](#) must each be non-zero. If isochronous posted requests may be generated in the system, then [D18F3x140\[IsocPreqTok\]](#) must also be non-zero. Or, in display refresh mode, [D18F3x140\[IsocReqTok, IsocRspTok\]](#) must be non-zero.

| Bits  | Description                                                                                                                                                                    |

### D18F3x17C Extended Freelist Buffer Count

Out of cold reset, the processor allocates a minimal number of buffers that is smaller than the default values in the register. BIOS must use D18F0x6C[RlsLnkFullTokCntImm] or D18F0x6C[RlsLnkFullTokCntOnRst] for the values in the register to take effect. This is necessary even if the values are unchanged from the default values.

| Bits | Description                                                                                                |
|------|------------------------------------------------------------------------------------------------------------|
| 31:4 | Reserved.                                                                                                  |

### D18F3x1A0 Core Interface Buffer Count

Out of cold reset, the processor allocates a minimal number of buffers that is smaller than the default values in the register. BIOS must use [D18F0x6C\[RlsLnkFullTokCntImm\]](#) or [D18F0x6C\[RlsLnkFullTokCntOnRst\]](#) for the values in the register to take effect. This is necessary even if the values are unchanged from the default values.

- The following buffer allocations rules must be satisfied:
  - CpuCmdBufCnt >= 2.

| 11:0  | <p><b>CSampleTimer.</b><br/>Read-write.<br/>Cold reset: 0.<br/>BIOS: 14h.</p> <p>Specifies the value that the internal CSampleTimer counter must increment to before expiring. When the internal CSampleTimer counter expires, it is reset to 0. This is the rate at which the northbridge samples the power monitor. A value of 0 disables the power monitor sampling. See FastCSampleTimer and <a href="#">2.5.9 [Application Power Management (APM)]</a>.</p> <p>When the Northbridge is in a low power state (<a href="#">D18F3x80/D18F3x84</a>[NbLowPwrEn]=1) and NbCof &gt;= RefClk, the Northbridge updates power information at the following rate:<br/> <math display="block">\text{CSampleTimer} * \text{FastCSampleTimer} \leq \text{Time} \leq (\text{CSampleTimer} * \text{FastCSampleTimer} + (9 * (\text{CLKIN} / \text{NbCof})) / \text{CLKIN}).</math></p> <p>When the Northbridge is in a low power state and NbCof &lt; RefClk, the Northbridge updates power information at the following rate:<br/> <math display="block">\text{CSampleTimer} * \text{FastCSampleTimer} \leq \text{Time} \leq (\text{CSampleTimer} * \text{FastCSampleTimer} + (9 * (\text{CLKIN} / \text{NbCof}) + 4) / \text{CLKIN}).</math></p> <p>When the Northbridge is not in a low power state, the Northbridge samples the power monitor at the following rate:<br/> <math display="block">\text{CSampleTimer} * \text{FastCSampleTimer} \leq \text{Time} \leq (\text{CSampleTimer} * \text{FastCSampleTimer} + (9 * (1 / \text{CLKIN})).</math></p> |

## D18F4x11[C:8] C-state Control

[D18F4x11\[C:8\]](#) consist of three identical 16-bit registers, one for each C-state Action Field (CAF) associated with an IO address that is read to enter C-states. Refer to [2.5.3.2 \[Core C-states\]](#).

- [D18F4x118](#)[15:0] specifies the actions attempted by the core when software reads from the IO address specified by [MSRC001\\_0073](#)[CstateAddr].
- [D18F4x118](#)[31:16] specifies the actions attempted by the core when software reads from the IO address specified by [MSRC001\\_0073](#)[CstateAddr]+1.
- [D18F4x11C](#)[15:0] specifies the actions attempted by the core when software reads from the IO address specified by [MSRC001\\_0073](#)[CstateAddr]+2.

Specifies the number of cores or compute units (see CstateCores) that must be in CC6 before an APM transition can occur to a boosted P-state that is higher performance than the P-state specified by CstateBoost. A value of 0 disables access to P-states above CstateBoost.</p>  |            |                    |    |                                          |    |                                                            |

|     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 8:6 | <b>CstateBoost.</b> Read-write. Reset: Fuse[CstateBoost]. Specifies the P-state which requires the number of cores or compute units (see CstateCores) specified in CstateCnt to be in CC6 before a transition to a higher performance (lower numbered) boosted P-state is allowed. CstateBoost must be less than or equal to D18F4x15C[NumBoostStates] otherwise undefined behavior results. If D18F4x15C[BoostLock]=1, CstateBoost can only be written with values that are greater than or equal to the reset value. Attempts to write values less than the reset value are ignored. A value of 0 indicates that the C-state boost feature is not supported. This field uses hardware P-state numbering. See 2.5.3.1.1.2 [Hardware P-state Numbering]. |
| 5   | <b>ApmTdpLimitSts: APM TDP limit status.</b> Read; set-by-hardware; write-1-to-clear. Reset: 0. This bit is set by hardware when D18F5xE8[ApmTdpLimit] changes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 4   | <b>ApmTdpLimitIntEn: APM TDP limit interrupt enable.</b> Read-write. Reset: 0. BIOS: 1. 1=Enables the generation of an interrupt using APIC330 of each core when D18F5xE8[ApmTdpLimit] changes. See ERBT-925 and ERBT-1049.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 3   | <b>TdpLimitDis.</b> IF D18F4x15C[BoostLock] THEN Read-only. ELSE Read-write. ENDIF. IF D0F0xBC_xC010408C[2]==1(Fuse[BapmDisable]). THEN BIOS:1. ENDIF. Reset: 0. 1=Disables TDP limit checking and allows the processor to transition to higher performance P-states. See 2.5.9.3 [Bidirectional Application Power Management (BAPM)].                                                                                                                                                                                                                                                                                                                                                                                                                   |

### D18F4x1C0 Node Cac Register 1

| Bits | Description                                                                                                                                                                                                                                                                                                                 |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 11:0 | <b>NodeCacLatest.</b> Read-only, updated-by-hardware. Reset: 0. Specifies the sum of all instantaneous power credits on each compute unit. NodeCacLatest is reset to 0 when D18F4x15C[ApmMasterEn]=0. NodeCacLatest is the sum of all CmpUnitCacLatest values. CmpUnitCacLatest is an internal, non-software visible value. |

### D18F4x250 TDP Limit 8

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31    | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 30:28 | <b>TdpLimitPstate.</b> Read-write. Reset: 0. Specifies the highest performance P-state that has a power consumption less than or equal to the APM TDP limit. This field is programmed by BIOS and uses software P-state numbering. See 2.5.3.1.1.1 [Software P-state Numbering] and 2.5.5.1.6 [Modification of P-state Requests and Visibility].                                                                                                                                                                                                                  |
| 27:12 | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 11:0  | <b>NodeTdpLimit.</b> Read-write; Same-for-all. Reset: Fuse[ChipTdpLimit]. Specifies the maximum allowed sum of TDPs from all cores on a node. If the consumed power exceeds the NodeTdpLimit, a P-state limit is applied to all cores on the processor to reduce the power consumption so that it remains within the TDP limit. If D18F4x15C[BoostLock]=1, NodeTdpLimit can only be written with values that are less than or equal to the reset value. Attempts to write an invalid value are ignored. See D18F4x16C[NodeTdpLimitEn] and 2.5.9.2 [TDP Limiting]. |

### 3.14 Device 18h Function 5 Configuration Registers

See 3.1 [Register Descriptions and Mnemonics]. See 2.7 [Configuration Space].

#### D18F5x00 Device/Vendor ID

| Bits  | Description                                          |
|-------|------------------------------------------------------|
| 31:16 | <b>DeviceID:</b> device ID. Read-only. Value: 1535h. |
| 15:0  | <b>VendorID:</b> vendor ID. Read-only. Value: 1022h. |

#### D18F5x04 Status/Command

| Bits  | Description                              |
|-------|------------------------------------------|
| 31:16 | <b>Status.</b> Read-only. Value: 0000h.  |
| 15:0  | <b>Command.</b> Read-only. Value: 0000h. |

#### D18F5x08 Class Code/Revision ID

| Bits | Description                                                                                                           |
|------|-----------------------------------------------------------------------------------------------------------------------|
| 31:8 | <b>ClassCode.</b> Read-only. Value: 060000h. Provides the host bridge class code as defined in the PCI specification. |
| 7:0  | <b>RevID:</b> revision ID. Read-only. Value: 00h.                                                                     |

#### D18F5x0C Header Type

| Bits | Description                                                                                                                                                                                     |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>HeaderTypeReg.</b> Read-only. Reset: 0080_0000h. These bits are fixed at their default values. The header type field indicates that there are not multiple functions present in this device. |

#### D18F5x34 Capabilities Pointer

| Bits | Description                                                 |
|------|-------------------------------------------------------------|
| 31:8 | Reserved.                                                   |
| 7:0  | <b>CapPtr:</b> capabilities pointer. Read-only. Value: 00h. |

#### D18F5x[70,60,50,40] Northbridge Performance Event Select Low

| Bits | Description                                                                                     |

#### D18F5x88 NB Configuration 4 (NB\_CFG4)

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 24   | <b>DisHbNpReqBusLock.</b> Read-write. Reset: 0. BIOS: 1. 0=While bus locks are in progress, all non-posted commands from I/O, including atomics, are blocked until the core has completed the locked transaction and releases the bus. 1=All non-posted commands except atomics do not honor bus locks and are allowed to proceed. This bit may be set to achieve better DMA performance in the presence of bus locks. This bit has no effect if <a href="#">MSRC001_001F[DisHbBusLock]</a> =1. |
| 18   | <b>EnCstateBoostBlockCC6Exit.</b> Read-write. Reset: 0. If (EnCstateBoostBlockCC6Exit==1 && <a href="#">MSRC001_001F[DisCstateBoostBlockPstateUp]</a> ==0), cores cannot exit CC6 until VDD is less than or equal to the voltage of the P-state indexed by <a href="#">D18F4x16C[CstateBoost]</a> . This bit must be cleared if <a href="#">CC6PstateLimitMaskDis</a> is set. This bit must be cleared if <a href="#">D18F3x18C[DisC6StpGntExit]</a> is set.                                    |
| 14   | <b>DisHldRegRdRspChk.</b> Read-write. Reset: 0. 1=Disable primary holding register CPU or I/O read response checks.                                                                                                                                                                                                                                                                                                                                                                             |
| 0    | <b>CC6PstateWakeUpDis.</b> Read-write. Reset: 0. BIOS: 1. 1=Disable waking up cores in CC6 for P-state changes. 0=Wakeup cores in CC6 for a P-state change to the PopDownPstate, and then return the core to CC6. This is a chicken bit for the case where a core can enter CC6 and not be in the PopDownPstate.                                                                                                                                                                                |

#### D18F5x8C NB Configuration 5 (NB\_CFG5)

| Bits | Description                                                                                                               |
|------|---------------------------------------------------------------------------------------------------------------------------|
| 15   | <b>EnSrqAllocGt31.</b> Read-write. Reset: 0b. BIOS: 1. 1=Enables allocation of SRA entries to above the lower 32 entries. |

#### D18F5xE0 Processor TDP Running Average

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3:0  | <b>RunAvgRange: running average range.</b> Read-write; <a href="#">Same-for-all</a> . Reset: 0. BIOS: 1h. Specifies the interval over which the UNB averages power consumption estimates from the cores for boosting. Time interval = $2^{(\text{RunAvgRange} + 1)} * \text{FreeRunSampleTimer}$ rate. A value of 0 disables the TDP running average accumulator capture function. See <a href="#">2.5.9 [Application Power Management (APM)]</a> and <a href="#">TdpRunAvgAccCap</a> . |

**D18F5xE8 TDP Limit 3**

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:29 | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 28:16 | <b>ApmTdpLimit</b> . Read-only; updated-by-hardware. Value: <a href="#">D18F4x250</a> [NodeTdpLimit]. If the consumed node power exceeds the ApmTdpLimit on an single node processor or the ApmTdpLimit/2 on a multi-node processor, a P-state limit is applied to all cores on all nodes to reduce the power consumption to remain within the TDP limit. See <a href="#">2.5.9.2 [TDP Limiting]</a> and <a href="#">MSRC001_0078</a> [ApmTdpLimit]. See <a href="#">D18F4x16C</a> [ApmlSwTdpLimitEn]. |
| 15:10 | <b>Tdp2Watt[5:0]</b> . Read-only. Value: 000000b. See Tdp2Watt[15:6]. Read by ucode to produce <a href="#">MSRC001_0077</a> [Tdp2Watt[5:0]].                                                                                                                                                                                                                                                                                                                                                           |
| 9:0   | <b>Tdp2Watt[15:6]</b> . Read-only. Value: Fuse[Tdp2Watt]. Specifies in watts/TDP units the conversion factor for converting TDP units to watts. Tdp2Watt[15:0] is a fixed point integer with 16 bits to the right of the decimal point and 0 bits to the left of the decimal point. E.g. Tdp2Watt[15]==0.5 W; Tdp2Watt[6]==0.976 mW; Tdp2Watt[0]==15.2 uW. Read by ucode to produce <a href="#">MSRC001_0077</a> [Tdp2Watt[15:6]].                                                                     |

### D18F5x16[C:0] Northbridge P-state [3:0]

Each of these registers specify the frequency and voltage associated with each of the NB P-states.

**Table 176: Register Mapping for D18F5x16[C:0]**

| Register  | Function     |
|-----------|--------------|
| D18F5x160 | NB P-state 0 |
| D18F5x164 | NB P-state 1 |
| D18F5x168 | NB P-state 2 |
| D18F5x16C | NB P-state 3 |

The NbVid field is allowed to be different between processors in a multi-processor system. All other fields are required to be programmed to the same value for all processors in the coherent fabric. See 2.5.4.1 [NB P-states] for more information about these registers.

**Table 177: NB P-state Definitions**

| Term            | Definition                                                                                                                         |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------|
| <b>NBCOF</b>    | NB current operating frequency in MHz. $NBCOF = 100 * (D18F5x16[C:0][NbFid] + 4h) / (2^{D18F5x16[C:0][NbDid]})$ .                  |
| <b>NBCOF[0]</b> | NB current operating frequency in MHz for NB P-state 0.<br>$NBCOF[0] = (100 * (D18F5x160[NbFid] + 4h) / (2^{D18F5x160[NbDid]}))$ . |

| 31    | <b>MemPstateDis: memory P-state disable.</b> IF (D18F3xE8[MemPstateCap] && D18F2x1B4[SmuCfgLock]==0) THEN Read-write, updated-by-hardware; Updated-by-SMU. ELSE Read-only, updated-by-hardware; Updated-by-SMU. Reset: Fuse[MemPstateDis]. 1=Memory P-state transitions are disabled. The current P-state is not changed by programming this bit. The memory P-state will be forced to M0 on the next NB P-state transition. On processors where memory P-states are enabled, programming this bit may result in a violation of bandwidth requirements stated in 2.5.3.1.5 (M0.MemClk-Freq>NBCOF). Software must ensure that NB P-states which violate those requirements are forced disabled. 0=Memory P-state transitions are enabled if D18F2x90_dct[0][DisDllShutdownSR]=0. |      |             |      |             |      |     |      |     |      |      |      |     |      |       |      |      |      |       |      |      |

### D18F5x178 Northbridge Fusion Configuration

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                             |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 19   | <b>SwGfxDis.</b> Read-write. Reset: 1. BIOS: IF ( <a href="#">GpuEnabled</a> ) THEN 0 ELSE 1 ENDIF. 1=Hardware handshakes for NB P-state transitions and DRAM self-refresh entry are ignored. See <a href="#">2.5.4.1.1 [NB P-state Transitions]</a> . See <a href="#">2.5.7.2 [DRAM Self-Refresh]</a> . Causes UNB to ignore AllowSelfRefresh, AllowNbTrans, ForceNbPs1, GnbSlow, and garlic flush.                    |
| 18   | <b>CstateFusionHsDis: C-state fusion handshake disable.</b> Read-write. Reset: 0. BIOS:1. 1=Ignore the FCH handshake response for PC6 transitions. 0=Use the FCH handshake response for PC6 entry. See <a href="#">2.5.3.2.4.1 [FCH Messaging]</a> .                                                                                                                                                                    |
| 17   | <b>Dis2ndGnbAllowPsWait.</b> Read-write. Reset: 0. BIOS: 1. 1=Do not do a second check of AllowNbTrans after quiescing the cores when transitioning NB P-states. See <a href="#">2.5.4.1.1 [NB P-state Transitions]</a> .                                                                                                                                                                                               |
| 16   | <b>ProcHotToGnbEn.</b> Read-write. Reset: 0. BIOS: 1. Specifies whether PROCHOT_L is distributed to GNB. See <a href="#">Figure 44</a> .                                                                                                                                                                                                                                                                                |
| 11   | <b>AllowSelfRefrS3Dis: allow self-refresh S3 disable.</b> Read-write. Reset: 0. BIOS: 1. 1=The NB does not wait for AllowSelfRefresh assertion before placing DRAM into self-refresh (see <a href="#">2.5.7.2 [DRAM Self-Refresh]</a> ) on S3 entry (see <a href="#">2.5.8.1.1 [ACPI Suspend to RAM State (S3)]</a> ). 0=The NB waits for AllowSelfRefresh assertion before placing DRAM into self-refresh on S3 entry. |

|    |                                                                                                                                                                                                                                                                                                                                                                                             |
|----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 10 | <b>InbWakeS3Dis: InbWake S3 disable.</b> Read-write. Reset: 0. BIOS: 1. 1= The NB does not wait for InbWake de-assertion before placing DRAM into self-refresh (see <a href="#">2.5.7.2 [DRAM Self-Refresh]</a> ) on S3 entry (see <a href="#">2.5.8.1.1 [ACPI Suspend to RAM State (S3)]</a> ). 0=The NB waits for InbWake de-assertion before placing DRAM into self-refresh on S3 entry. |
| 3  | <b>CstateThreeWayHsEn: C-state three way handshake disable.</b> Read-write. Reset: 0. 1=Enable the three way handshake with the FCH when entering a C-state. 0=Only a two way handshake with FCH is used. There is no message about the resulting package state sent to FCH. See <a href="#">2.5.3.2.4.1 [FCH Messaging]</a> .                                                              |
| 2  | <b>CstateFusionDis: C-state fusion disable.</b> Read-write. Reset: 0. 1=All HALT or C-state requests are forwarded to the FCH. 0=HALT and C-state requests are forwarded to the FCH when each core has made a request. See <a href="#">2.5.3.2.4.1 [FCH Messaging]</a> .                                                                                                                    |

### D18F5x17C Miscellaneous Voltages

| Bits  | Description                                                                                                                                                                                                                                                                                                                            |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31    | <b>NbPsi0VidEn: Northbridge PSI0_L VID enable.</b> Read-write. Reset: 0. This bit specifies how PSI0_L is controlled for VDDNB. See <a href="#">D18F3xA0[PsiVidEn]</a> and <a href="#">2.5.1.3.1 [PSIx_L Bit]</a> .                                                                                                                    |
| 30:23 | <b>NbPsi0Vid[7:0]: Northbridge PSI0_L VID threshold.</b> Read-write. Reset: 0. When enabled by NbPsi0VidEn, NbPsi0Vid specifies the threshold value of the VID code generated by the Northbridge, which in turn determines the state of PSI0_L. See <a href="#">D18F3xA0[PsiVid[6:0]]</a> and <a href="#">2.5.1.3.1 [PSIx_L Bit]</a> . |
| 22:18 | Reserved.                                                                                                                                                                                                                                                                                                                              |
| 17:10 | <b>MinVid: minimum voltage.</b> Read-only. Reset: Fuse[MinVid]. Specifies the VID code corresponding to the minimum voltage (highest VID code) that the processor drives. 00h indicates that no minimum VID code is specified. See <a href="#">2.5.1 [Processor Power Planes And Voltage Control]</a> .                                |
| 9:8   | Reserved.                                                                                                                                                                                                                                                                                                                              |
| 7:0   | <b>MaxVid: maximum voltage.</b> Read-only. Reset: Fuse[MaxVid]. Specifies the VID code corresponding to the maximum voltage (lowest VID code) that the processor drives. 00h indicates that no maximum VID code is specified. See <a href="#">2.5.1 [Processor Power Planes And Voltage Control]</a> .                                 |

## D18F5x194 Name String Address Port

[D18F5x194](#) and [D18F5x198](#) provide BIOS with a read-only (Fused) name string that may be copied to [MSRC001\\_00](#)[35:30] at warm reset. Each of [D18F5x198\\_x](#)[B:0] is read as follows:

1. Write [D18F5x194](#)[Index].
2. Read [D18F5x198](#).

**D18F5x240 ECC Exclusion Base Address Low**

- Transaction addresses are within the defined range if:  
{EccExclBaseAddr[47:6], 00\_0000b} <= address[47:0] <= {EccExclLimitAddr[47:6], 00\_0000b}.
- BIOS must quiesce all other forms of DRAM traffic when configuring this range. See [MSRC001\\_001F](#)[DisDramScrub].
- When initializing the base/limit pair, the BIOS must write the limit register before the EccExclEn bit is set. BIOS should clear EccExclEn before changing the address range.
- BIOS should take care to re-initialize memory with valid ECC when resizing this region.

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:6 | <b>EccExclBaseAddr[31:6]: ECC exclusion base address register bits[31:6].</b> Read-write. Reset: 0. EccExclBaseAddr[47:6]={ <a href="#">D18F5x244</a> [EccExclBaseAddr[47:32]], EccExclBaseAddr[31:6]}. The ECC Exclusion Base/Limit Address registers setup a contiguous range in DRAM where ECC check and error reporting is disabled. BIOS configures the ECC exclusion range code to cover the frame buffer region in ECC UMA systems with internal GPUs. The GPU is configured as MC_SHARED:MC_VM_STEERING [DEFAULT_STEERING]=1 (system traffic to onion). |

### 3.15 GPU Memory Mapped Registers

### 3.16 Northbridge IOAPIC Registers

The Northbridge IOAPIC is accessed through the Northbridge IOAPIC base address specified by [D0F0xFC\\_x01 \[IOAPIC Base Address Lower\]](#) and [D0F0xFC\\_x02 \[IOAPIC Base Address Upper\]](#).

#### NBIOAPICx00 IO Register Select

| Bits | Description                                                                                                                                |

### NBIOAPICx20 IRQ Pin Assertion

| Bits | Description                                                                                                                                                                                                                                                                                                         |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:8 | Reserved.                                                                                                                                                                                                                                                                                                           |
| 7:0  | <b>InputIrq.</b> Read-write. Reset: 0. IRQ number for the requested interrupt. A write to this register will trigger an interrupt associated with the redirection table entry referenced by the IRQ number. Currently the redirection table has 24 entries. Writes with IRQ number greater than 17h have no effect. |

### NBIOAPICx40 EOI

| Bits | Description                                                                                                                                                                                                                                                                   |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:8 | Reserved.                                                                                                                                                                                                                                                                     |
| 7:0  | <b>Vector.</b> Write-only. Reset: 0. Interrupt vector. A write to this register will clear the remote IRR bit in the redirection table entry found matching the interrupt vector. This provides an alternate mechanism other than PCI special cycle for EOI to reach IOxAPIC. |

### 3.17 APIC Registers

See 2.4.8.1.2 [APIC Register Space].

MMIO local APIC space is accessible in xAPIC mode.

#### APIC20 APIC ID

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                          |

| 31:8 | RAZ.                                                                                                                                                                                                                                                                              |
| 7:0  | <b>Priority.</b> Reset: 0. Read-only. Indicates the core's current priority servicing a task or interrupt, and is used to determine if any pending interrupts should be serviced. It is the higher value of the task priority value and the current highest in-service interrupt. |

**APICB0 End of Interrupt**

This register is written by the software interrupt handler to indicate the servicing of the current interrupt is complete.

| Bits | Description         |
|------|---------------------|
| 31:0 | Unused. Write-only. |

**APICC0 Remote Read**

| Bits | Description                                                                                                                        |
|------|------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>RemoteReadData.</b> Read-only. Reset: 0. The data resulting from a valid completion of a remote read inter-processor interrupt. |

**APICD0 Logical Destination (LDR)**

| Bits  | Description                                                                                                                              |
|-------|------------------------------------------------------------------------------------------------------------------------------------------|
| 31:24 | <b>Destination.</b> Read-write. Reset: 0. This APIC's destination identification. Used to determine which interrupts should be accepted. |
| 23:0  | Reserved.                                                                                                                                |

**APICE0 Destination Format**

Only supported in xAPIC mode.

| Bits        | Description                                                                                                                                                                                                                                                                                                                                                               |             |                   |    |                               |       |          |    |                            |

| 9     | <b>FocusDisable.</b> Read-write. Reset: 0. 1=Disable focus core checking during lowest-priority arbitrated interrupts. AMD-specific: Deprecated by Intel with x2APIC, not deprecated by AMD.                                                                                                                                                                                                                               |
| 8     | <b>APICSWEn: APIC software enable.</b> Read-write. Reset: 0. 0=SMI, NMI, INIT, LINT[1:0], and Startup interrupts may be accepted; pending interrupts in <a href="#">APIC[170:100]</a> and <a href="#">APIC[270:200]</a> are held, but further fixed, lowest-priority, and ExtInt interrupts are not accepted. All LVT entry mask bits are set and cannot be cleared.<br>See <a href="#">MSRC001_001F</a> [DisApicSwEnFix]. |
| 7:0   | <b>Vector.</b> Read-write. Reset: FFh. The vector that is sent to the core in the event of a spurious interrupt. The behavior of bits 3:0 are controlled as specified by <a href="#">D18F0x68</a> [ApicExtSpur].                                                                                                                                                                                                           |

### APIC[170:100] In-Service (ISR)

The in-service registers provide a bit per interrupt to indicate that the corresponding interrupt is being serviced by the core. APIC100[15:0] are reserved. Interrupts are mapped as follows:

Table 178: [Register Mapping](#) for [APIC\[170:100\]](#)

| Register | Function             |
|----------|----------------------|
| APIC100  | Interrupts [31:16]   |
| APIC110  | Interrupts [63:32]   |
| APIC120  | Interrupts [95:64]   |
| APIC130  | Interrupts [127:96]  |
| APIC140  | Interrupts [159:128] |
| APIC150  | Interrupts [191:160] |
| APIC160  | Interrupts [223:192] |
| APIC170  | Interrupts [255:224] |

| Bits | Description                                                                                                                   |
|------|-------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>InServiceBits.</b> Reset: 0. Read-only. These bits are set when the corresponding interrupt is being serviced by the core. |

### APIC[1F0:180] Trigger Mode (TMR)

The trigger mode registers provide a bit per interrupt to indicate the assertion mode of each interrupt. APIC180[15:0] are reserved. Interrupts are mapped as follows:

Table 179: [Register Mapping](#) for APIC[1F0:180]

| Register | Function             |
|----------|----------------------|
| APIC180  | Interrupts [31:16]   |
| APIC190  | Interrupts [63:32]   |
| APIC1A0  | Interrupts [95:64]   |
| APIC1B0  | Interrupts [127:96]  |
| APIC1C0  | Interrupts [159:128] |
| APIC1D0  | Interrupts [191:160] |
| APIC1E0  | Interrupts [223:192] |
| APIC1F0  | Interrupts [255:224] |

| Bits | Description                                                                                                                                                                                        |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>TriggerModeBits.</b> Reset: 0. Read-only. The corresponding trigger mode bit is updated when an interrupt is accepted. The values are: 0=Edge-triggered interrupt. 1=Level-triggered interrupt. |

### APIC[270:200] Interrupt Request (IRR)

The interrupt request registers provide a bit per interrupt to indicate that the corresponding interrupt has been accepted by the APIC. APIC200[15:0] are reserved. Interrupts are mapped as follows:

Table 180: [Register Mapping](#) for APIC[270:200]

| Register | Function             |
|----------|----------------------|
| APIC200  | Interrupts [31:16]   |
| APIC210  | Interrupts [63:32]   |
| APIC220  | Interrupts [95:64]   |
| APIC230  | Interrupts [127:96]  |
| APIC240  | Interrupts [159:128] |
| APIC250  | Interrupts [191:160] |
| APIC260  | Interrupts [223:192] |
| APIC270  | Interrupts [255:224] |

| Bits | Description                                                                                                                  |
|------|------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>RequestBits.</b> Read-only. Reset: 0. The corresponding request bit is set when the an interrupt is accepted by the APIC. |

### APIC280 Error Status

Writes to this register trigger an update of the register state. The value written by software is arbitrary. Each write causes the internal error state to be loaded into this register, clearing the internal error state. Consequently, a second write prior to the occurrence of another error causes the register to be overwritten with cleared data.

| Bits | Description |

| 31:8 | RAZ.        |

|     |                                                                                                                                                                                                                                                                      |
|-----|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7   | <b>IllegalRegAddr: illegal register address.</b> Read-write. Reset: 0. This bit indicates that an access to a nonexistent register location within this APIC was attempted. Can only be set in xAPIC mode. Illegal register accesses in x2APIC mode cause #GP fault. |
| 6   | <b>RcvdIllegalVector: received illegal vector.</b> Read-write. Reset: 0. This bit indicates that this APIC has received a message with an illegal vector (00h to 0Fh for fixed and lowest priority interrupts).                                                      |
| 5   | <b>SentIllegalVector.</b> Read-write. Reset: 0. This bit indicates that this APIC attempted to send a message with an illegal vector (00h to 0Fh for fixed and lowest priority interrupts).                                                                          |
| 4   | RAZ. Intel defined as Redirectable IPI. Intel dropped redirectable IPI with the addition of x2APIC. Redirectable not deprecated by AMD.                                                                                                                              |
| 3   | <b>RcvAcceptError: receive accept error.</b> Read-write. Reset: 0. This bit indicates that a message received by this APIC was not accepted by this or any other APIC. AMD-specific: Deprecated by Intel with x2APIC, not deprecated by AMD.                         |
| 2   | <b>SendAcceptError.</b> Read-write. Reset: 0. This bit indicates that a message sent by this APIC was not accepted by any APIC. AMD-specific: Deprecated by Intel with x2APIC, not deprecated by AMD.                                                                |
| 1:0 | RAZ. [1]: Previously defined as Receive Checksum Error. Only used by 3-wire interface. [0]: Previously defined as Send Checksum Error. Only used by 3-wire interface.                                                                                                |

#### APIC300 Interrupt Command Low (ICR Low)

Not all combinations of ICR fields are valid. Only the following combinations are valid:

**Table 181: ICR valid combinations**

| Message Type                    | Trigger Mode | Level  | Destination Shorthand              |
|---------------------------------|--------------|--------|------------------------------------|
| Fixed                           | Edge         | x      | x                                  |
|                                 | Level        | Assert | x                                  |
| Lowest Priority, SMI, NMI, INIT | Edge         | x      | Destination or all excluding self. |
|                                 | Level        | Assert | Destination or all excluding self  |
| Startup                         | x            | x      | Destination or all excluding self  |

Note: x indicates a don't care.

| 12    | <b>DS: interrupt delivery status.</b> Read-only; updated-by-hardware. Reset: 0. 0=Idle. 1=Send pending. (Indicates that the interrupt has not yet been accepted by the core.) |
| 11    | RAZ.                                                                                                                                                                          |
| 10:8  | <b>MsgType: message type.</b> Read-write. Reset: 000b. See <a href="#">2.4.8.1.14 [Generalized Local Vector Table]</a> .                                                      |
| 7:0   | <b>Vector.</b> Read-write. Reset: 00h. Interrupt vector number.                                                                                                               |

**APIC380 Timer Initial Count**

| Bits | Description                                                                                                                |
|------|----------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>Count.</b> Read-write. Reset: 0. The value copied into the current count register when the timer is loaded or reloaded. |

### APIC390 Timer Current Count

| Bits | Description                                                          |
|------|----------------------------------------------------------------------|
| 31:0 | <b>Count.</b> Read-only. Reset: 0. The current value of the counter. |

### APIC3E0 Timer Divide Configuration

The Div bits are encoded as follows:

**Table 183: Div[3,1:0] Value Table**

| Div[3] | Div[1:0] | Resulting Timer Divide |
|--------|----------|------------------------|
| 0      | 00b      | 2                      |
| 0      | 01b      | 4                      |
| 0      | 10b      | 8                      |
| 0      | 11b      | 16                     |
| 1      | 00b      | 32                     |
| 1      | 01b      | 64                     |
| 1      | 10b      | 128                    |
| 1      | 11b      | 1                      |

| Bits | Description                                                            |
|------|------------------------------------------------------------------------|
| 31:4 | RAZ.                                                                   |
| 3    | <b>Div[3].</b> Read-write. Reset: 0. See <a href="#">Table 183</a> .   |
| 2    | RAZ.                                                                   |
| 1:0  | <b>Div[1:0].</b> Read-write. Reset: 0. See <a href="#">Table 183</a> . |

### APIC400 Extended APIC Feature

| Bits  | Description                                                                                                                                                                                                          |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:24 | RAZ.                                                                                                                                                                                                                 |
| 23:16 | <b>ExtLvtCount: extended local vector table count.</b> Read-only. Reset: 04h. This specifies the number of extended LVT registers ( <a href="#">APIC[530:500]</a> ) in the local APIC.                               |
| 15:3  | RAZ.                                                                                                                                                                                                                 |
| 2     | <b>ExtApicIdCap: extended APIC ID capable.</b> Read-only. Reset: 1. 1=The processor is capable of supporting an 8-bit APIC ID, as controlled by <a href="#">APIC410[ExtApicIdEn]</a> .                               |
| 1     | <b>SeoiCap: specific end of interrupt capable.</b> Read-only. Reset: 1. 1=The <a href="#">APIC420 [Specific End Of Interrupt]</a> is present.                                                                        |
| 0     | <b>IerCap: interrupt enable register capable.</b> Read-only. Reset: 1. This bit indicates that the <a href="#">APIC[4F0:480] [Interrupt Enable]</a> are present. See <a href="#">2.4.8.1.8 [Interrupt Masking]</a> . |

## APIC410 Extended APIC Control

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| 31:8 | RAZ.                                                                                                                                                                                                                                                                  |
| 7:0  | <b>EoiVec: end of interrupt vector.</b> Read-write. Reset: 0. A write to this field causes an end of interrupt cycle to be performed for the vector specified in this field. The behavior is undefined if no interrupt is pending for the specified interrupt vector. |

## APIC[4F0:480] Interrupt Enable

AMD-Specific. Interrupt enables range is mapped as follows:

Table 184: [Register Mapping](#) for APIC[4F0:480]

| Register | Function       |
|----------|----------------|
| APIC480  | IntEn[31:0]    |
| APIC490  | IntEn[63:32]   |
| APIC4A0  | IntEn[95:64]   |
| APIC4B0  | IntEn[127:96]  |
| APIC4C0  | IntEn[159:128] |
| APIC4D0  | IntEn[191:160] |
| APIC4E0  | IntEn[223:192] |
| APIC4F0  | IntEn[255:224] |

| Bits | Description                                                                                                                                             |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>InterruptEnableBits.</b> Read-write. Reset: FFFF_FFFFh. The interrupt enable bits can be used to enable each of the 256 interrupts. See above table. |

## APIC[530:500] Extended Interrupt [3:0] Local Vector Table

AMD-Specific. APIC500 provides a local vector table entry for IBS; See [D18F3x1CC](#). APIC510 provides a

local vector table entry for error thresholding. The APIC[530:520] registers are unused. [APIC\[530:500\]](#) interrupts disabled by ([MSRC001\\_001F](#)[DisApicExtReg]==1).

Table 185: [Register Mapping](#) for [APIC\[530:500\]](#)

| Register | Function                            |
|----------|-------------------------------------|
| APIC500  | Extended Interrupt 0 (IBS)          |
| APIC510  | Extended Interrupt 1 (Thresholding) |
| APIC520  | Extended Interrupt 2                |
| APIC530  | Extended Interrupt 3                |

| Bits  | Description                                                                                                                                                                                                                                            |

| 7:0   | <b>Vector.</b> IF ( <a href="#">MSRC001_001F</a> [DisApicExtReg]) THEN RAZ. ELSE Read-write. ENDIF. Reset: 00h. Interrupt vector number.                                                                                                               |

### 3.18 CPUID Instruction Registers

Processor feature capabilities and configuration information are provided through the CPUID instruction. The information is accessed by (1) selecting the CPUID function setting EAX and optionally ECX for some functions, (2) executing the CPUID instruction, and (3) reading the results in the EAX, EBX, ECX, and EDX registers. The syntax *CPUID FnXXXX\_XXXX\_EiX[\_xYYY]* refers to the function where EAX==X, and optionally ECX==Y, and the registers specified by EiX. EiX can be any single register such as {EAX, EBX, ECX, and EDX}, or a range of registers, such as E[C,B,A]X. Undefined function numbers return 0's in all 4 registers. See [2.4.10 \[CPUID Instruction\]](#).

Unless otherwise specified, single-bit feature fields are encoded as 1=Feature is supported by the processor; 0=Feature is not supported by the processor.

The following provides processor specific details about CPUID.

#### **CPUID Fn0000\_0000\_EAX Processor Vendor and Largest Standard Function Number**

| Bits | Description                                                                                                                                               |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>LFuncStd: largest standard function.</b> Value: 0000_000Dh. The largest CPUID standard function input value supported by the processor implementation. |

**CPUID Fn0000\_0000\_E[D,C,B]X Processor Vendor**

CPUID Fn0000\_0000\_E[D,C,B]X and CPUID Fn8000\_0000\_E[D,C,B]X return the same value.

**Table 186: Reset Mapping for CPUID Fn8000\_0000\_E[D,C,B]X**

| Register              | Value      | Description                     |
|-----------------------|------------|---------------------------------|
| CPUID Fn0000_0000_EBX | 6874_7541h | The ASCII characters “h t u A”. |
| CPUID Fn0000_0000_ECX | 444D_4163h | The ASCII characters “D M A c”. |
| CPUID Fn0000_0000_EDX | 6974_6E65h | The ASCII characters “i t n e”. |

| Bits | Description                                                                            |
|------|----------------------------------------------------------------------------------------|
| 31:0 | <b>Vendor.</b> The 12 8-bit ASCII character codes to create the string “AuthenticAMD”. |

**CPUID Fn0000\_0001\_EAX Family, Model, Stepping Identifiers**

Also see CPUID Fn8000\_0001\_EAX [Family, Model, Stepping Identifiers].

**Family** is an 8-bit value and is defined as: **Family[7:0]** = ({0000b, BaseFamily[3:0]} + ExtendedFamily[7:0]). E.g. If BaseFamily[3:0]=Fh and ExtendedFamily[7:0]=07h, then Family[7:0]=16h.

**Model** is an 8-bit value and is defined as: **Model[7:0]** = {ExtendedModel[3:0], BaseModel[3:0]}. E.g. If ExtendedModel[3:0]=Eh and BaseModel[3:0]=8h, then Model[7:0] = E8h. Model numbers vary with product.

| Bits  | Description                                                                                             |
|-------|---------------------------------------------------------------------------------------------------------|
| 31:28 | Reserved.                                                                                               |
| 27:20 | <b>ExtFamily: extended family.</b> CPUID Fn0000_0001_EAX[ExtFamily] is an alias of D18F3xFC[ExtFamily]. |
| 19:16 | <b>ExtModel: extended model.</b> CPUID Fn0000_0001_EAX[ExtModel] is an alias of D18F3xFC[ExtModel].     |
| 15:12 | Reserved.                                                                                               |
| 11:8  | <b>BaseFamily.</b> CPUID Fn0000_0001_EAX[BaseFamily] is an alias of D18F3xFC[BaseFamily].               |
| 7:4   | <b>BaseModel.</b> CPUID Fn0000_0001_EAX[BaseModel] is an alias of D18F3xFC[BaseModel].                  |
| 3:0   | <b>Stepping.</b> CPUID Fn0000_0001_EAX[Stepping] is an alias of D18F3xFC[Stepping].                     |

**CPUID Fn0000\_0001\_EBX LocalApicId, LogicalProcessorCount, CLFlush**

| Bits  | Description                                                                                                                                                                   |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:24 | <b>LocalApicId: initial local APIC physical ID.</b> Value: The initial APIC20[ApicId] value. See 2.4.4 [Processor Cores and Downcoring].                                      |
| 23:16 | <b>LogicalProcessorCount: logical processor count.</b> Specifies the number of cores in the processor as CPUID Fn8000_0008_ECX[NC] + 1. Value: CPUID Fn8000_0008_ECX[NC] + 1. |
| 15:8  | <b>CLFlush: CLFLUSH size in quadwords.</b> Value: 08h.                                                                                                                        |
| 7:0   | <b>8BitBrandId: 8 bit brand ID.</b> Value: 00h. Indicates that the brand ID is in CPUID Fn8000_0001_EBX.                                                                      |

**CPUID Fn0000\_0001\_ECX Feature Identifiers**

### 3.19 MSRs - MSR0000\_XXXX

See 3.1 [Register Descriptions and Mnemonics] for a description of the register naming convention. MSRs are accessed through x86 WRMSR and RDMSR instructions.

#### MSR0000\_0000 Load-Store MCA Address

| Bits | Description                             |
|------|-----------------------------------------|
| 63:0 | Alias of <a href="#">MSR0000_0402</a> . |

#### MSR0000\_0001 Load-Store MCA Status

| Bits | Description                             |
|------|-----------------------------------------|
| 63:0 | Alias of <a href="#">MSR0000_0401</a> . |

#### MSR0000\_0010 Time Stamp Counter (TSC)

Reset: 0000\_0000\_0000\_0000h. [MSR0000\\_0010](#)[31:0] is derived from [D18F3x130](#)[TSC[31:0]].  
[MSR0000\\_0010](#)[63:32] is derived from [D18F3x134](#)[TSC[63:32]].

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 63:32 | <b>TSC[63:32]: time stamp counter high.</b> See: TSC[31:0].                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 31:0  | <b>TSC[31:0]: time stamp counter low.</b> Read-write; updated-by-hardware; S3-check-exclude. TSC[63:0] = { TSC[63:32],TSC[31:0]}. The TSC increments at the P0 frequency. This field uses software P-state numbering. See 2.5.3.1.1.1 [Software P-state Numbering]. The TSC counts at the same rate in all P-states, all C states, S0, or S1. A read of this MSR in guest mode is affected by <a href="#">MSRC000_0104</a> [Time Stamp Counter Ratio (TscRateMsr)]. The value (TSC/TSCRatio) is the TSC P0 frequency based value (as if TSCRatio==1.0) when (TSCRatio!=1.0). |

#### MSR0000\_001B APIC Base Address (APIC\_BAR)

| Bits  | Description                                                                                                                                                                                                                                   |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 63:40 | MBZ.                                                                                                                                                                                                                                          |
| 39:12 | <b>ApicBar[39:12]: APIC base address register.</b> Read-write. Reset: 00_FEE0_0h. Specifies the base address, physical address [39:12], for the APICXX register set in xAPIC mode. See 2.4.8.1.2 [APIC Register Space].                       |
| 11    | <b>ApicEn: APIC enable.</b> Read-write. Reset: 0. See 2.4.8.1.2 [APIC Register Space]. 1=Local APIC is enabled in xAPIC mode. Intel warm reset state. <a href="#">MSR0000_001B</a> [ApicEn] is aliased to <a href="#">D18F3x108</a> [ApicEn]. |
| 10    | MBZ.                                                                                                                                                                                                                                          |
| 9     | MBZ.                                                                                                                                                                                                                                          |
| 8     | <b>BSC: boot strap core.</b> Read-write; updated-by-hardware. Reset: x. 1=The core is the boot core of the BSP. 0=The core is not the boot core of the BSP.                                                                                   |
| 7:0   | MBZ.                                                                                                                                                                                                                                          |

**MSR0000\_002A Cluster ID (EBL\_CR\_POWERON)**

Read; GP-write. Writes to this register result in a GP fault with error code 0.

| Bits  | Description                                                                                                                                                          |

| 2    | <b>MCIP: machine check in progress.</b> Read-write; set-by-hardware. 1=A machine check is in progress.                                                                                                                                                                                                                                                                                                                                   |
| 1    | <b>EIPV: error instruction pointer valid.</b> Read-write; Updated-by-hardware. 1=The instruction pointer that was pushed onto the stack by the machine check mechanism references the instruction that caused the machine check error.                                                                                                                                                                                                   |
| 0    | <b>RIPV: restart instruction pointer valid.</b> Read-write; Updated-by-hardware. 1=Program execution can be reliably restarted at the EIP address on the stack. 0=The interrupt was not precise and/or the process (task) context may be corrupt; continued operation of this process may not be possible without intervention, however system processing or other processes may be able to continue with appropriate software clean up. |

**MSR0000\_017B Global Machine Check Exception Reporting Control (MCG\_CTL)**

Read-write. Not shared. Reset: 0000\_0000\_0000\_0000h. This registers controls enablement of the individual error reporting banks; see 2.14.1 [Machine Check Architecture]. When a machine check register bank is not enabled in MCG\_CTL, errors for that bank are not logged or reported, and actions enabled through the MCA are not taken; each MCI\_CTL register identifies which errors are still corrected when MCG\_CTL[i] is disabled.

| Bits | Description                                                                                                                                                                                                |

| 63:0 | <b>LastIntToIP.</b> Holds the target RIP of the last branch that occurred before the exception or interrupt. |

**MSR0000\_020[F:0] Variable-Size MTRRs Base/Mask**

Each MTRR ([MSR0000\\_020\[F:0\] \[Variable-Size MTRRs Base/Mask\]](#), [MSR0000\\_02\[6F:68,59:58,50\]](#), or [MSR0000\\_02FF \[MTRR Default Memory Type \(MTRRdefType\)\]](#)) specifies a physical address range and a corresponding memory type (MemType) associated with that range. Setting the memory type to an unsupported value results in a #GP.

The variable-size MTRRs come in pairs of base and mask registers (MSR0000\_0200 and MSR0000\_0201 are the first pair, etc.). Variables MTRRs are enabled through [MSR0000\\_02FF\[MtrrDefTypeEn\]](#). A core access--with address CPUAddr--is determined to be within the address range of a variable-size MTRR if the following equation is true:

$\text{CPUAddr}[39:12] \& \text{PhyMask}[39:12] == \text{PhyBase}[39:12] \& \text{PhyMask}[39:12]$ .

For example, if the variable MTRR spans 256 KB and starts at the 1 MB address. The PhyBase would be set to 0\_0010\_0000h and the PhyMask to F\_FFFC\_0000h (with zeros filling in for bits[11:0]). This results in a range from 0\_0010\_0000h to 0\_0013\_FFFF.

**MSR0000\_020[E,C,A,8,6,4,2,0] Variable-Size MTRRs Base**

### MSR0000\_0277 Page Attribute Table (PAT)

This register specifies the memory type based on the PAT, PCD, and PWT bits in the virtual address page tables.

| Bits  | Description                                                                                   |

| 63   | <b>Val: error valid.</b> Read-write; set-by-hardware. Cold reset: 0. 1=This bit indicates that a valid error has been detected. This bit should be cleared to 0 by software after the register has been read.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 62   | <p><b>Overflow: error overflow.</b> Read-write; set-by-hardware. Cold reset: 0. 1=An error was detected while the valid bit (Val) was set; at least one error was not logged. Overflow is set independently of whether the existing error is overwritten.</p> <p>The following hierarchy identifies the error logging priorities.</p> <ol style="list-style-type: none"> <li>1. Uncorrectable errors</li> <li>2. Correctable errors</li> </ol> <p>The machine check mechanism handles the contents of MCi_STATUS during overflow as follows:</p> <ul style="list-style-type: none"> <li>• Higher priority errors overwrite lower priority errors.</li> <li>• New errors of equal or lower priority do not overwrite existing errors.</li> <li>• Uncorrectable errors which are not logged due to overflow result in setting PCC, unless the new uncorrectable error is of the same type and in the same reportable address range as the existing error.</li> </ul> <p>Implementation note: Uncorrectable errors require software intervention. When an uncorrectable error occurs, the software must take action to prevent possible data corruption. However, if software cannot obtain the details of the error, it must behave pessimistically. Lost uncorrectable errors are signaled by Overflow and PCC; when software sees PCC, it considers the situation as fatal to the system. New uncorrectable errors of the same type and in the same reportable address range as existing errors may avoid setting PCC, even when setting Overflow.</p> |
| 61   | <b>UC: error uncorrected.</b> Read-write; Updated-by-hardware. | 57    | <b>PCC: processor context corrupt.</b> Read-write; Updated-by-hardware. Cold reset: 0. 1=Hardware context held by the processor may have been corrupted. Continued operation of the system may have unpredictable results. The error is not recoverable or survivable, and the system should be reinitialized. See <a href="#">2.14.1.6.1 [Differentiation Between System-Fatal and Process-Fatal Errors]</a> .<br><br>Implementation note 1: PCC errors are fatal to the system. Therefore, it is important not to set PCC unnecessarily. If the error results in global processor state which is no longer reliable or which may contain incorrect global information (e.g., corrupted cache tag, corrupted address), then PCC should be set to prevent random corruption. If the error affects only a single or known set of processes (e.g., corrupted data with good address and tags), then PCC should not be set.<br><br>Implementation note 2: Errors which are imprecise do not automatically require PCC; as long as the error can be confined to a process, system operation can be salvaged and PCC should not be set. An imprecise interrupt is signalled by RIPV=0.<br><br>Implementation note 3: Hardware must consider the effects of CPL when setting PCC. Hardware must ensure that the CPL reported on the MCA interrupt stack is the same as when the error occurred; if the value of CPL changes between the error and the MCE, the error was not contained and PCC should be set to 1. It is sufficient to ensure that the CPL has not changed from supervisor to user, as it is most important to identify if the error happened when the kernel was running. |                    |                        |

| Read Data Error                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |       | An error occurred during an attempted read of data from the NB. Possible reasons include master abort and target abort.                                                                                                                                                                                                                                                         | SRDE             |                  |                  |
| Data or Tag Parity                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |       | An IC data or tag array parity error for a tag hit occurred during instruction fetch from the IC. The data is discarded from the IC, the data array and all tag arrays are cleared, and the line is refetched. IC parity errors may occur on non-cacheable instructions. Non-cacheable instructions pass through the instruction cache but are not marked as valid cache lines. | IDP, ITP         |                  |                  |

**MSR0000\_0406 MC1 Machine Check Address (MC1\_ADDR)**

Read-write; Updated-by-hardware. Cold reset: 0000\_0000\_0000\_0000h. The MCi\_ADDR register contains valid data if indicated by MCi\_STATUS[AddrV]. See 2.14.1 [Machine Check Architecture].

| Bits | Description                          |
|------|--------------------------------------|
| 63:0 | <b>ADDR:</b> Address. See Table 200. |

The following table defines the address register as a function of error type.

**Table 200: MC1 Address Register**

| Error Type                | Error Sub-Type | Bits  | Description            |
|---------------------------|----------------|-------|------------------------|
| IC Data and Tag Parity    |                | 47:4  | Linear address         |
| Tag Snoop                 |                | 39:6  | Physical address       |
| Victim Parity             |                | 47:6  | Linear Address         |
| BTLB Parity               |                | 47:4  | Linear address         |
| BTLB Multimatch           |                |       |                        |
| PRPE PatchRam ParityError |                | 12:0  | Patch Ram Address      |
| BU Read Data Error        | -              | 63:40 | Reserved.              |
|                           |                | 39:6  | <b>PhysAddr[47:6].</b> |

|------------------|--------|-----------------------------------------------------------------------------------------|---------------------------------------|------------------|------------------|
| NB               | IBUFF  | A parity error occurred in the IBUFF.                                                   | IBUFF                                 | -                | E <sup>1</sup>   |
| NB               | OBUFF  | A parity error occurred in the OBUFF.                                                   | OBUFF                                 | -                | E <sup>1</sup>   |
| L2 Cache         | L2Tag  | A correctable or uncorrectable ECC error was seen in the L2 tag.                        | TagCor,<br>TagUncor                   | -                | E <sup>1</sup>   |
| L2 Cache         | L2Data | A correctable or uncorrectable ECC error was seen in the L2 data array.                 | DataParity,<br>DataCor,<br>DataUncor. | -                | E <sup>1</sup>   |
| Attribute Parity | Par    | A parity error was seen in the L2 attribute bits. This error was corrected by hardware. | AttrParity                            | A <sup>2</sup>   | E <sup>1</sup>   |

1. EAC: The error action is taken if detected for all CU errors. D=Error action taken if detected. E=Error action taken if MCA bank enabled. See [2.14.1.3 \[Error Detection, Action, Logging, and Reporting\]](#). If any core in the L2 complex has MCG\_CTL[2] asserted, the MCA logic in the L2I is enabled.
2. CID: core ID. A=Error reported to the affected core. 0=Error reported to core 0 of the L2 complex; see [2.14.1.3 \[Error Detection, Action, Logging, and Reporting\]](#).
3. See [MSR0000\\_0408](#).
4. Error Action: [Sync flood](#)=Take sync flood if PCC=1. None=No action other than that specified by MCA.

**MSR0000\_040A MC2 Machine Check Address (MC2\_ADDR)**

Read-write; Updated-by-hardware. Cold reset: 0000\_0000\_0000\_0000h. See 2.14.1 [Machine Check Architecture]. The following table defines the address register as a function of error type.

This register is shared by all cores of the L2 complex when the **MSRC001\_10A0**[McaToMstCoreEn]==0.

When (**MSRC001\_10A0**[McaToMstCoreEn]==1), only the lowest enabled core in the complex can read/write this register. All other cores will read all 0s and writes will be ignored.

| 63:0 | Reserved.   |

**MSR0000\_0410 MC4 Machine Check Control (MC4\_CTL)**Read-write; [Not-same-for-all](#). Reset: 0000\_0000\_0000\_0000h.

**MSR0000\_0410**[31:0] is an alias of **D18F3x40**, which is accessible through PCI configuration space. Only one of these registers exists in multi-core devices; see 3.1.1 [Northbridge MSRs In Multi-Core Products]. Accessibility of this register by non-NBC cores is affected by **D18F3x44**[NbMcaToMstCpuEn].

See **D18F3x44** [MCA NB Configuration] for further NB MCA configuration controls. See 2.14.1 [Machine Check Architecture] for a general description of the machine check architecture. See **MSRC001\_0048** [NB Machine Check Control Mask (MC4\_CTL\_MASK)] for the corresponding error mask register.

| 17    | <b>CpPktDatEn: completion packet error reporting enable.</b> Read-write. 1=Enables MCA reporting of completion packets with the EP bit set. Any response packet with data errors detected by ONION will generate this error.                                                                                                                                                                                                                                                                                                                                     |
| 16    | <b>NbIntProtEn: northbridge internal bus (ONION) protocol error reporting enable.</b> Read-write. 1=Enables MCA reporting of protocol errors detected on the northbridge internal bus (ONION). When possible, this enable should be cleared before initiating a warm reset to avoid logging spurious errors due to RESET_L signal skew.                                                                                                                                                                                                                          |
| 15:13 | Unused. Read-write.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 12    | <b>WDTRptEn: watchdog timer error reporting enable.</b> 1=Enables MCA reporting of watchdog timer errors. The watchdog timer checks for NB system accesses for which a response is expected but no response is received. See <b>D18F3x44</b> [MCA NB Configuration] for information regarding configuration of the watchdog timer duration. This bit does not affect operation of the watchdog timer in terms of its ability to complete an access that would otherwise cause a system hang. This bit only affects whether such errors are reported through MCA. |
| 11    | <b>AtomicRMWEn: atomic read-modify-write error reporting enable.</b> 1=Enables MCA reporting of atomic read-modify-write (RMW) commands received from an IO link. Atomic RMW commands are not supported. An atomic RMW command results in a link error response being generated back to the requesting IO device. The generation of the link error response is not affected by this bit.                                                                                                                                                                         |

| 1   | <b>UECCEn: uncorrectable ECC error reporting enable.</b> 1=Enables MCA reporting of DDR3 DRAM uncorrectable ECC errors which are detected in the NB. In some cases data may be forwarded to the core prior to checking ECC in which case the check takes place in one of the other error reporting banks. |
| 0   | <b>CECCEn: correctable ECC error reporting enable.</b> 1=Enables MCA reporting of DDR3 DRAM correctable ECC errors which are detected in the NB.                                                                                                                                                          |

### MSR0000\_0411 MC4 Machine Check Status (MC4\_STATUS)

**Not-same-for-all.** Cold reset: 0000\_0000\_0000\_0000h.

**MSR0000\_0411**[63:32] is an alias of **D18F3x4C**, and **MSR0000\_0411**[31:0] is an alias of **D18F3x48**. Only one of these registers exists in multi-core devices; see 3.1.1 [Northbridge MSRs In Multi-Core Products]. Accessibility of this register by non-NBC cores is affected by **D18F3x44**[NbMcaToMstCpuEn]. See **MSRC001\_0015**[McStatusWrEn] for information on writing to this register. See 2.14.1 [Machine Check Architecture] for machine check architecture background.

Table 204 describes each error type. Table 205 and Table 206 describe the error codes and status register settings for each error type.

| Bits  | Description                                                                                                                                                                                                                                                                                                                                          |

| 57    | <b>PCC: processor context corrupt.</b> See: <b>MSR0000_0401</b> [PCC].                                                                                                                                                                                                                                                                               |
| 56    | <b>ErrCoreIdVal: error core ID is valid.</b> Read-write; set-by-hardware. 1=The ErrCoreId field is valid.                                                                                                                                                                                                                                            |
| 55    | Reserved. Placeholder for TCC.                                                                                                                                                                                                                                                                                                                       |
| 54:47 | <b>Syndrome[7:0].</b> Read-write. Syndrome[15:0] = {Syndrome[15:8], Syndrome[7:0]}. The syndrome bits when an ECC error is detected. See Table 206 Valid Syndrome column for which bits are valid for each error.                                                                                                                                    |
| 46    | <b>CECC: correctable ECC error.</b> Read-write; Updated-by-hardware. 1=The error was a correctable ECC error according to the restrictions of the ECC algorithm. UC indicates whether the error was actually corrected by the processor. If CECC is set with UECC, indicates that an error was detected by the hardware-managed history scheme.      |
| 45    | <b>UECC: uncorrectable ECC error.</b> Read-write; Updated-by-hardware. 1=The error was an uncorrectable ECC error according to the restrictions of the ECC algorithm. UC indicates whether the error was actually corrected by the processor. If UECC is set with CECC, indicates that an error was detected by the hardware-managed history scheme. |

|       |                                                                                                                                                                                                                                                                                                      |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 44    | <b>Deferred: deferred error.</b> Read-write; Updated-by-hardware. 1=A deferred error was created. A deferred error is the result of an uncorrectable data error which did not immediately cause a processor exception; the data is poisoned and an exception is deferred until the data is consumed. |
| 43:42 | Reserved.                                                                                                                                                                                                                                                                                            |
| 41    | <b>SubLink: sublink.</b> Read-write; set-by-hardware. For errors associated with a link, this bit indicates if the error was associated with the upper or lower byte of the link. 0=Sublink [7:0]. 1=Sublink [15:8].                                                                                 |
| 40    | <b>Scrub: error detected on a scrub.</b> Read-write; Set-by-hardware.                                                                                                                                                                                                                                |
| 35:32 | <b>ErrCoreId: error associated with core N.</b> Read-write; updated-by-hardware. When ErrCoreIdVal=1 this field indicates which core within the processor is associated with the error; Otherwise this field is reserved. All values greater than <a href="#">D18F5x84</a> [CmpCap] are reserved.    |
| 31:24 | Reserved. Read-write.                                                                                                                                                                                                                                                                                |
| 23:21 | Reserved.                                                                                                                                                                                                                                                                                            |
| 20:16 | <b>ErrorCodeExt: extended error code.</b> Read-write; Updated-by-hardware. See <a href="#">MSR0000_0401</a> [ErrorCodeExt]. See <a href="#">Table 205</a> for values.                                                                                                                                |
| 15:0  | <b>ErrorCode: error code.</b> Read-write; Updated-by-hardware. See <a href="#">2.14.1.5 [Error Code]</a> .                                                                                                                                                                                           |

**Table 204: MC4 Error Descriptions**

| Error Type     | Description                                                                                                                                                                                                                                                                                           | CTL <sup>1</sup>  | ETG <sup>2</sup> | EAC <sup>4</sup> |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|------------------|------------------|
| Sync Error     | Link-defined sync error packets detected on link. The NB floods its outgoing links with sync packets after detecting a sync packet on an incoming link independent of the state of the control bits.                                                                                                  | SyncPktEn         | L                | D                |
| Master Abort   | Master abort seen as result of link operation. Reasons for this error include requests to non-existent addresses. The NB returns an error response back to the requestor with any associated data all 1s independent of the state of the control bit.                                                 | MstrAbortEn       | L                | D                |
| Target Abort   | Target abort seen as result of link operation. The NB returns an error response back to the requestor with any associated data all 1s independent of the state of the control bit.                                                                                                                    | TgtAbortEn        | L                | D                |
| RMW Error      | An atomic read-modify-write (RMW) command was received from an IO link. Atomic RMW commands are not supported. An atomic RMW command results in a link error response being generated back to the requesting IO device. The generation of the link error response is not affected by the control bit. | AtomicRMWEn       | L                | D                |
| WDT Error      | NB WDT timeout due to lack of progress. The NB WDT monitors transaction completions. A transaction that exceeds the programmed time limit reports errors via the MCA. The cause of error may be another node or device which failed to respond.                                                       | WDTRptEn          | L                | D                |
| DRAM ECC Error | A DRAM ECC error detected.                                                                                                                                                                                                                                                                            | CECCEn,<br>UECCEn | D                | D                |
| DRAM CRC Error | A DRAM CRC error was detected.                                                                                                                                                                                                                                                                        | CCRCEn,<br>UCRCEn | D                | D                |

**Table 204: MC4 Error Descriptions**

| Error Type                                                                                                                                                                                                                                                                                                                                                                                                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | CTL <sup>1</sup>               | ETG <sup>2</sup> | EAC <sup>4</sup> |

**MSR0000\_0412 MC4 Machine Check Address (MC4\_ADDR)**

IF (D18F3x44[NbMcaToMstCpuEn] && !NBC) THEN RAZ; Per-node; not-same-for-all. ELSE Read-write; Per-node; not-same-for-all. ENDIF. Cold reset: 0000\_0000\_0000\_0000h. See 2.14.1 [Machine Check Architecture]. MSR0000\_0412[31:0] is an alias of D18F3x50. MSR0000\_0412[63:32] is an alias of D18F3x54.

Only one of these registers exists in multi-core devices; see [3.1.1 \[Northbridge MSRs In Multi-Core Products\]](#). ErrAddr[47:1] carries supplemental information associated with a machine check error, generally the address being accessed. Accessibility of this register by non-NBC cores is affected by [D18F3x44\[NbMcaToMstCpuEn\]](#). The format of ErrAddr[47:1] is a function of [MSR0000\\_0411\[ErrorCodeExt\]](#); See ErrAddr[47:1].

The register format depends on the type of error being logged:

- Protocol errors contain the error reason code, may contain the physical address, and are formatted according to [Table 208](#).
- NB array errors indicate the array in error, and are formatted according to [Table 210](#).
- NB Watchdog timer errors depend on the mode selected by [D18F3x180\[McaLogErrAddrWdtErr\]](#), and the format is indicated by [D18F3x4C\[AddrV\]](#). If [D18F3x4C\[AddrV\]](#) is indicated, errors are formatted according to [Table 207](#). If [D18F3x4C\[AddrV\]](#) is not indicated, errors are formatted according to [Table 212](#).
- All other NB errors which indicate [D18F3x4C\[AddrV\]](#) are formatted according to [Table 207](#).

Table 207: Format of [MSR0000\\_0412](#)[ErrAddr[47:1]] for All Other Errors

This field is encoded identically to the “Code” field for link transactions defined in the link specification.                                                                                                                                                                                                                                                                                                                                     |             |                    |         |                |         |               |     |                                         |         |          |     |                    |         |          |         |                                                                                        |

**MSR0000\_0413 NB Machine Check Misc 4 (DRAM Thresholding) 0 (MC4\_MISC0)**

[MSR0000\\_0413](#) is the first of the NB machine check miscellaneous registers. [MSR0000\\_0413](#) is associated with the DRAM error type. To see the remaining NB machine check miscellaneous registers, refer to [MSR0000\\_0408](#). Only one of these registers exists in multi-core devices; see [3.1.1 \[Northbridge MSRs In Multi-Core Products\]](#).

| 1. Causes shutdown. See <a href="#">2.14.1.3.1 [MCA conditions that cause Shutdown]</a> . PRNF errors will hang the core.<br>2. Causes shutdown if UC=1. See <a href="#">2.14.1.3.1 [MCA conditions that cause Shutdown]</a> .<br>3. STATQ sets PCC=1 if a store retired in last 3 cycles or FpTokenRet bits mismatch. |                |                  |            |           |    |      |       |    |    |       |       |     |      |      |

**MSR0000\_0416 MC5 Machine Check Address (MC5\_ADDR)**

Read-write; Updated-by-hardware. Cold reset: 0000\_0000\_0000\_0000h. The MCi\_ADDR register contains valid data if indicated by MCi\_STATUS[AddrV]. See [2.14.1 \[Machine Check Architecture\]](#). The register format depends on the type of error being logged.

| Bits | Description                                   |
|------|-----------------------------------------------|
| 63:0 | <b>ADDR</b> . See <a href="#">Table 215</a> . |

The following tables define the address register as a function of error type.

**Table 215: MC5 Address Register**

| Error Type | Error Sub-Type       | Bits  | Description                                                                                                  |
|------------|----------------------|-------|--------------------------------------------------------------------------------------------------------------|
| WDT        | - (ErrorCodeExt=00h) | 63:48 | Reserved                                                                                                     |
|            |                      | 48:0  | <b>LogAddr[48:0]</b> . Logical canonical address of the next instruction after the last instruction retired. |

**MSR0000\_0417 MC5 Machine Check Miscellaneous (MC5\_MISC)**

Cold reset: 0000\_0000\_0000\_0000h.

| Bits       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |            |                   |     |                                                               |     |                                                               |     |                                                               |     |                                                      |     |                                                       |     |                                                       |     |                                                       |     |                                              |

| 14    | <b>FFXSE: fast FXSAVE/FRSTOR enable.</b> Read-write. Reset: 0. 1=Enables the fast FXSAVE/FRSTOR mechanism. A 64-bit operating system may enable the fast FXSAVE/FRSTOR mechanism if ( <a href="#">CPUID Fn8000_0001_EDX</a> [FFXSR]==1)). This bit is set once by the operating system and its value is not changed afterwards. |
| 13    | <b>LMSLE: long mode segment limit enable.</b> Read-write. Reset: 0. 1=Enables the long mode segment limit check mechanism.                                                                                                                                                                                                      |
| 12    | <b>SVME: secure virtual machine (SVM) enable.</b> IF ( <a href="#">MSRC001_0114</a> [SvmeDisable]==1) THEN MBZ. ELSE Read-write. ENDIF. Reset: 0. 1=SVM features are enabled.                                                                                                                                                   |
| 11    | <b>NXE: no-execute page enable.</b> Read-write. Reset: 0. 1=The no-execute page protection feature is enabled.                                                                                                                                                                                                                  |
| 10    | <b>LMA: long mode active.</b> Read-only. Reset: 0. 1=Indicates that long mode is active.                                                                                                                                                                                                                                        |
| 9     | MBZ.                                                                                                                                                                                                                                                                                                                            |
| 8     | <b>LME: long mode enable.</b> Read-write. Reset: 0. 1=Long mode is enabled.                                                                                                                                                                                                                                                     |
| 7:1   | RAZ.                                                                                                                                                                                                                                                                                                                            |
| 0     | <b>SYSCALL: system call extension enable.</b> Read-write. Reset: 0. 1=SYSCALL and SYSRET instructions are enabled. This adds the SYSCALL and SYSRET instructions which can be used in flat addressed operating systems as low latency system calls and returns.                                                                 |

**MSRC000\_0081 SYSCALL Target Address (STAR)**

Reset: 0000\_0000\_0000\_0000h. This register holds the target address used by the SYSCALL instruction and the code and stack segment selector bases used by the SYSCALL and SYSRET instructions.

| Bits  | Description                                        |
|-------|----------------------------------------------------|
| 63:48 | <b>SysRetSel: SYSRET CS and SS.</b> Read-write.    |
| 47:32 | <b>SysCallSel: SYSCALL CS and SS.</b> Read-write.  |
| 31:0  | <b>Target: SYSCALL target address.</b> Read-write. |

**MSRC000\_0082 Long Mode SYSCALL Target Address (STAR64)**

Reset: 0000\_0000\_0000\_0000h.

| Bits | Description                                                                                                                                                                                                |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 63:0 | <b>LSTAR: long mode target address.</b> Read-write. Target address for 64-bit mode calling programs. The address stored in this register must be in canonical form (if not canonical, a #GP fault occurs). |

**MSRC000\_0083 Compatibility Mode SYSCALL Target Address (STARCOMPAT)**

Reset: 0000\_0000\_0000\_0000h.

| Bits | Description                                                                                                                                                                                               |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 63:0 | <b>CSTAR: compatibility mode target address.</b> Read-write. Target address for compatibility mode. The address stored in this register must be in canonical form (if not canonical, a #GP fault occurs). |

**MSRC000\_0084 SYSCALL Flag Mask (SYSCALL\_FLAG\_MASK)**

| Bits  | Description                                                                                                                                                                                                      |
|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 63:32 | RAZ.                                                                                                                                                                                                             |
| 31:0  | <b>Mask: SYSCALL flag mask.</b> Read-write. Reset: 0000_0000h. This register holds the EFLAGS mask used by the SYSCALL instruction. 1=Clear the corresponding EFLAGS bit when executing the SYSCALL instruction. |

**MSRC000\_0100 FS Base (FS\_BASE)**

Reset: 0000\_0000\_0000\_0000h.

| Bits | Description                                                                                                                                                                                                                                             |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 63:0 | <b>FSBase: expanded FS segment base.</b> Read-write; not-same-for-all. This register provides access to the expanded 64-bit FS segment base. The address stored in this register must be in canonical form (if not canonical, a #GP fault fill occurs). |

**MSRC000\_0101 GS Base (GS\_BASE)**

Reset: 0000\_0000\_0000\_0000h.

| Bits | Description                                                                                                                                                                                                                                             |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 63:0 | <b>GSBase: expanded GS segment base.</b> Read-write; not-same-for-all. This register provides access to the expanded 64-bit GS segment base. The address stored in this register must be in canonical form (if not canonical, a #GP fault fill occurs). |

**MSRC000\_0102 Kernel GS Base (KernelGSbase)**

Reset: 0000\_0000\_0000\_0000h.

| Bits | Description                                                                                                                                                                                                                                                                                              |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 63:0 | <b>KernelGSBase: kernel data structure pointer.</b> Read-write. This register holds the kernel data structure pointer which can be swapped with the GS_BASE register using the SwapGS instruction. The address stored in this register must be in canonical form (if not canonical, a #GP fault occurs). |

**MSRC000\_0103 Auxiliary Time Stamp Counter (TSC\_AUX)**

Reset: 0000\_0000\_0000\_0000h.
